INTEGRATED WASTEWATER AND SEPTAGE MANAGEMENT
A PLANNING APPROACH

DRAFT

PART A: PRESENTATION SLIDES
ABOUT NATIONAL FAECAL SLUDGE AND SEPTAGE MANAGEMENT ALLIANCE (NFSSMA)

The ‘NFSSM Alliance’ was formed with a vision to “Create an enabling environment which amplifies scaling of safe, sustainable and inclusive FSSM through knowledge, partnerships and innovative solutions by 2024”.

Convened by Bill and Melinda Gates Foundation in 2016, the Alliance is a voluntary body that aims to:

- Build consensus and drive the discourse on FSSM at a policy level, and
- Promote peer learning among members to achieve synergies for scaled implementation and reduce duplication of efforts.

The Alliance currently comprises 28 organizations across the country working towards solutions for Indian states and cities. The Alliance works in close collaboration with the Ministry of Housing and Urban Affairs (MoHUA) and several state and city governments through its members to support the progress and derive actions towards mainstreaming of FSSM at state and national level. The NFSSM Alliance works on all aspects of city sanitation plans to regulatory and institutional frameworks across the sanitation value chain. The NFSSM Alliance working in collaboration with the Ministry of Housing and Urban Affairs has been instrumental in the passage of India’s First Policy on FSSM launched in 2017. This resulted in 19 out of 36 states adopting guidelines and policies for FSSM in India.

The strength of the Alliance lies in its diverse membership, which includes research institutes, academic institutions, think-tanks, quasi-government bodies, implementing organizations data experts, consultants and intermediaries. This enabled a multi-disciplinary view of urban sanitation, with members building on each other’s expertise. The alliance has had enormous success in championing FSSM as a viable solution to the Government of India by broadly focussing on:

1. Influencing and informing policy.
2. Demonstrating success through innovation and pilots.
3. Building capacities of key stakeholders across the value chain.

The collaborative continues to work towards promoting the FSSM agenda through policy recommendations and sharing best practices which are inclusive, comprehensive, and have buy-in from several stakeholders in the sector.
ABOUT TRAINING MODULE REVIEW COMMITTEE (TMRC)

To ensure quality control in content and delivery of trainings and capacity building efforts, a Training Module Review Committee (TMRC) was formed with the collaborative effort of all Alliance partners. TMRC which is anchored by National Institute of Urban Affairs (NIUA), has the following broad objectives:

- Identification of priority stakeholders and accordingly training modules for Capacity Building.
- Development of a Normative Framework – For Capacity Building at State Level.
- Standardization of priority training modules – appropriate standardization of content with flexibility for customization based on State context.
- Quality Control of Trainings – criteria for ensuring minimum quality of training content and delivery.
- Strategy for measuring impact of trainings and capacity building efforts.
# About the Training Module

<table>
<thead>
<tr>
<th>Title</th>
<th>Integrated Wastewater and Septage Management — A Planning Approach (Part A: Presentation Slides)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Purpose</strong></td>
<td>This module is created to address the challenge faced by the ULBs in wastewater management along with the faecal sludge and septage management. The septic tank effluent along with the grey water produced at the household level is not safely disposed on site in many cities. This is usually let out into the stormwater drains and gets disposed off into the environment in a haphazard manner. This module focusses on managing the domestic liquid effluent at a city level along with faecal sludge and septage management, thereby allowing to cater to the sanitation needs of the households in a complete manner. The training also thereby addressed the challenges faced by ULBs in achieving the ODF++ stage, which expects complete management of liquid waste in the city.</td>
</tr>
<tr>
<td><strong>Target Audience</strong></td>
<td>ULB or parastatal agency officials such as engineers and planners who are involved in managing of wastewater and preparing city sanitation plans, early professionals who wish to develop career into Wastewater Management.</td>
</tr>
</tbody>
</table>
| **Learning Objectives** | 1. To create a strong foundation of sustainable sanitation and water management.  
2. To understand the sanitation system approach for holistically looking at the management of waste products and identify the current challenges.  
3. To be updated with the technological solutions available in the market for wastewater management.  
4. To understand the treatment mechanisms and processes involved in different technologies used for wastewater treatment. |
| **Format of the Module** | The training module is based on Case Methodology where in the sessions will be combined with exercises based on real-life cases. This helps the trainee to apply the knowledge grasped during the session and reinforce it further. The module is divided into three parts:  
**Part A:** This contains the slides used during the session in the presentation format.  
**Part B:** This is a comprehensive compilation of the all the session briefs and further reading material which helps to strengthen the learning.  
**Part C:** This contains the exercise developed for training based on the real-life cases. |
<p>| <strong>Duration</strong> | In a face to face training format, this training is conceptualized for 3 days without site visits and can be adopted for including the site visits depending upon the city where it is being conducted. |</p>
<table>
<thead>
<tr>
<th>Glossary Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anal cleansing water</td>
<td>Water used to cleanse oneself after defecating and/or urinating; it is generated by those who use water, rather than dry material, for anal cleansing. The volume of water used per cleaning typically ranges from 0.5 L to 3 L.</td>
</tr>
<tr>
<td>Anaerobic Digestion</td>
<td>The degradation and stabilization of organic compounds by microorganisms in the absence of oxygen, leading to production of biogas</td>
</tr>
<tr>
<td>Biogas</td>
<td>Common name for the mixture of gases released from anaerobic digestion. Biogas is comprised of methane (50 to 75%), carbon dioxide (25 to 50%) and varying quantities of nitrogen, hydrogen sulphide, water vapour and other components. Biogas can be collected and burned for fuel (like propane).</td>
</tr>
<tr>
<td>Biomass</td>
<td>Refers to plants or animals cultivated using the water and/or nutrients flowing through a sanitation system. The term Biomass may include fish, insects, vegetables, fruit, forage or other beneficial crops that can be utilized for food, feed, fibre and fuel production. Blackwater is the mixture of urine, faeces and flush water along with anal cleansing water.</td>
</tr>
<tr>
<td>Blackwater</td>
<td>Contains the pathogens of faeces and the nutrients of urine that are diluted in the flush water</td>
</tr>
<tr>
<td>Brown water</td>
<td>Mixture of faeces and flush water, and does not contain urine. It is generated by Urine-Diverting Flush Toilets and, therefore, the volume depends on the volume of the flush water used. The pathogen and nutrient load of Faeces is not reduced, only diluted by the flush water. Brown water may also include Anal Cleansing Water (if water is used for cleansing) and/or Dry Cleansing Materials</td>
</tr>
<tr>
<td>Collection and Storage/Treatment</td>
<td>Describes the ways of collecting, storing, and sometimes treating the products generated at the User Interface. The treatment provided by these technologies is often a function of storage and is usually passive (e.g., requiring no energy input). Thus, products that are ‘treated’ by these technologies often require subsequent treatment before Use and/or disposal.</td>
</tr>
<tr>
<td>Compost</td>
<td>Decomposed organic matter that results from a controlled aerobic degradation process. In this biological process, microorganisms (mainly bacteria and fungi) decompose the biodegradable waste components and produce an earth-like, odourless, brown/black material. Compost has excellent soil-conditioning properties and a variable nutrient content. Because of leaching and volatilization, some of the nutrients may be lost, but the material is still rich in nutrients and organic matter. Generally, Excreta or Sludge should be composted long enough (2 to 4 months) under thermophilic conditions (55 to 60 °C) in order to be sanitized sufficiently for safe agricultural use. This temperature is not guaranteed in most Composting Chambers, but considerable pathogen reduction can normally be achieved.</td>
</tr>
<tr>
<td>Conveyance</td>
<td>Describes the transport of products from one functional group to another. Although products may need to be transferred in various ways between functional groups, the longest and most important gap is between User Interface or Collection and Storage/Treatment and (Semi-) Centralized Treatment. Therefore, for the sake of simplicity, conveyance only describes the technologies used to transport products between these functional groups</td>
</tr>
<tr>
<td><strong>Dewatering</strong></td>
<td>The process of reducing the water content of a sludge or slurry. Dewatered sludge may still have a significant moisture content, but it typically is dry enough to be conveyed as a solid (e.g., shovelled).</td>
</tr>
<tr>
<td><strong>Dried Faeces</strong></td>
<td>Faeces that have been dehydrated until they become a dry, crumbly material. Dehydration takes place by storing Faeces in a dry environment with good ventilation, high temperatures and/or the presence of absorbent material. Very little degradation occurs during dehydration and this means that the Dried Faeces are still rich in organic matter. However, Faeces reduce by around 75% in volume during dehydration and most pathogens die off. There is a small risk that some pathogenic organisms can be reactivated under the right conditions, particularly, in humid environments.</td>
</tr>
<tr>
<td><strong>Dry Cleansing Materials</strong></td>
<td>Solid materials used to cleanse oneself after defecating and/or urinating (e.g., paper, leaves, corncobs, rags or stones). Depending on the system, Dry Cleansing Materials may be collected and separately disposed of. Although extremely important, a separate product name for menstrual hygiene products like sanitary napkins and tampons is not included in this Compendium. In general (though not always), they should be treated along with the solid waste generated in the household.</td>
</tr>
<tr>
<td><strong>Effluent</strong></td>
<td>General term for a liquid that leaves a technology, typically after Blackwater or Sludge has undergone solids separation or some other type of treatment. Effluent originates at either a Collection and Storage or a (Semi-) Centralized Treatment technology. Depending on the type of treatment, the Effluent may be completely sanitized or may require further treatment before it can be used or disposed of.</td>
</tr>
<tr>
<td><strong>Excreta</strong></td>
<td>Consists of Urine and Faeces that is not mixed with any Flushwater. Excreta is small in volume, but concentrated in both nutrients and pathogens. Depending on the quality of the faeces, it has a soft or runny consistency.</td>
</tr>
<tr>
<td><strong>Faeces</strong></td>
<td>Refers to (semi-solid) excrement that is not mixed with Urine or water. Depending on diet, each person produces approximately 50 L per year of faecal matter. Fresh faeces contain about 80% water. Of the total nutrients excreted, Faeces contain about 12% N, 39% P, 26% K and have 107 to 109 faecal coliforms in 100 mL.</td>
</tr>
<tr>
<td><strong>Flushwater</strong></td>
<td>The water discharged into the User Interface to transport the content and/or clean it. Freshwater, rainwater, recycled. Greywater, or any combination of the three can be used as a Flushwater source.</td>
</tr>
<tr>
<td><strong>Greywater</strong></td>
<td>The total volume of water generated from washing food, clothes and dishware, as well as from bathing, but not from toilets. It may contain traces of Excreta (e.g., from washing diapers) and, therefore, also pathogens. Greywater accounts for approximately 65% of the wastewater produced in households with flush toilets.</td>
</tr>
<tr>
<td><strong>Nutrient</strong></td>
<td>Any substance that is used for growth. Nitrogen (N), phosphorus (P) and potassium (K) are the main nutrients contained in agricultural fertilizers. N and P are also primarily responsible for the eutrophication of water bodies.</td>
</tr>
<tr>
<td><strong>Sanitation</strong></td>
<td>The means of safely collecting and hygienically disposing of excreta and liquid wastes for the protection of public health and the preservation of the quality of public water bodies and, more generally, of the environment.</td>
</tr>
<tr>
<td>(Semi-) Centralized Treatment</td>
<td>Refers to treatment technologies that are generally appropriate for large user groups (i.e., neighbourhood to city level applications). The operation, maintenance, and energy requirements of technologies within this functional group are generally higher than for smaller-scale technologies at the S level. The technologies are divided into 2 groups: T.1-T.12 are primarily for the treatment of Blackwater, Brown water, Greywater or Effluent, whereas T.13-T.17 are mainly for the treatment of Sludge. Technologies for pre-treatment and post-treatment are also described (technology information sheets PRE and POST).</td>
</tr>
<tr>
<td>User Interface</td>
<td>Describes the type of toilet, pedestal, pan, or urinal with which the user comes in contact; it is the way by which the user accesses the sanitation system. In many cases, the choice of User Interface will depend on the availability of water. Note that greywater and Stormwater do not originate at the User Interface, but may be treated along with the products that originate from it.</td>
</tr>
<tr>
<td>Use and/or Disposal</td>
<td>Refers to the methods by which products are ultimately returned to the environment, either as useful resources or reduced-risk materials. Furthermore, products can also be cycled back into a system (e.g., by using treated Greywater for flushing).</td>
</tr>

Sustainable Sanitation & Water Management
1. Sustainable Sanitation & Water Management

**Learning objectives**

- To understand the concept of Environmental Health and Environmental Services needed to maintain the balance in the environment.
- To understand Environmental Sanitation and four Environmental Services needed to achieve its objectives.
- To understand the types of Liquid Waste Products and their flow.
- To understand the basis of Ecological Sanitation and its extension.
- To understand Urban Challenges faced at various levels of sanitation and water management.

**Contents**

- Environmental Health
- Environmental Sanitation
- Waste Products and their flow
- EcoSan Concept
- Urban Challenges
1.1 Introduction to Environmental Health

**Definition**

Field of science that studies how the environment influences human health and disease.

Environment consists of

The physical, chemical, biological and social features of our surroundings

Environmental Health is the field of science that studies how the environment influences human health and disease. “Environment,” in this context, means things in the natural environment like air, water and soil, and also all the physical, chemical, biological and social features of our surroundings. Features such as physical form, chemical and biological composition etc. provides characteristics to the environment and helps us to classify them.
Good health presupposes that the water we drink, the air we breathe and the food we eat are free from contaminants and pathogens, and that facilities, services and hygienic behaviour provide for a clean environment in which to live, with measures to break the cycle of disease and contamination.

- Health is best protected by safeguarding the environment by pollution prevention and provision of an environmental service to each household or community.
- Individual health benefits from enough clean and safe drinking water. This can be attained by clean water sources or reliable water treatment.
- Community health can only be reached if waste is collected, recycled, treated or disposed of in a sanitary manner.

Environmental Health

To achieve the objectives one must;

- Maintain a natural environment free from undue hazards
- Ensure a built environment free from undue hazards
- Provide environmental services to households and communities

Environmental Services

It include the provision of raw materials and energy used to produce goods and services, as well as the removal of waste from human activities, and their role in life support and landscape maintenance.
Creating, changing and altering the natural and built environment has an impact on environmental health. Hence, to be able achieve the objectives of environmental health following things are recommended:

- While altering the natural environment, care must be taken that it is free from undue hazards.
- While creating elements in built environment, it needs to be ensured that these elements are free from hazards.
- In order to maintain the equilibrium between the two environments, environmental services needs to be provided to the household and communities.

Anyone changing the natural or built environment has an impact on environmental health! To achieve good environmental health, one should:

- Maintain a natural environment free from undue hazards.
- Ensure a built environment free from undue hazards.
- Provide essential environmental services to households and communities in order to achieve good individual and community health.

Ecological sanitation commonly known as Ecosan has three fundamental aspects: (a) rendering human excreta safe, (b) preventing pollution rather than attempting to control it after we pollute, and (c) using the safe products of sanitized human excreta for agricultural purposes. This approach fits in the definition of circular economy and can be characterized as “Sanitize-and-recycle”.

By treating and recycling the waste such as human excreta, pollution of the water cycle is avoided. Thus, the Ecosan concept goes a long way in contributing to sustaining environmental health.

The natural and built environment with its natural resources water, air and soil (blue); all services and facilities are required to keep the environment clean and protect health (green). Our focus is on water supply and environmental sanitation services, facilities and human behaviour (inside yellow line). 

**Contents of Environmental Health**

![Diagram of Environmental Health](source: Eawag/Sandec 2008)
1.2 Environmental Sanitation

There are many possible definitions of sanitation. Sanitation means the safe management of human excreta and wastewater. It therefore includes both the ‘hardware’ (e.g. latrines and sewers) and the ‘software’ (regulation, hygiene promotion) needed to reduce faecal-oral disease transmission. It encompasses potential reuse, ultimate disposal of human excreta or discharge of wastewater.
Most diseases associated with water supply and sanitation, such as diarrhoea, are spread by pathogens (disease-causing organisms) found in human excreta (faeces and urine). The faecal-oral mechanism, in which some of the faeces of an infected individual are transmitted to the mouth of a new host through one of a variety of routes, is by far the most significant transmission mechanism. This mechanism works through a variety of routes, as shown by the so-called “F Diagram”.

Primary interventions with the greatest impact on health often relate to the management of faeces at the household level. This is because (a) a large percentage of hygiene-related activity takes place in or close to the home and (b) first steps to improving hygienic practices are often easiest to implement at the household level.

Secondary barriers are hygiene practices preventing faecal pathogens, which have entered the environment via stools or on hands, from multiplying and reaching new hosts. Secondary barriers thus include washing hands before preparing food or eating, and preparing, cooking, storing, and re-heating food in such a way as to avoid pathogen survival and multiplication.
Environmental sanitation aims at improving the quality of life of the individuals and at contributing to social development. This includes disposal or hygienic management of liquid and solid human waste, control of disease vectors and provision of washing facilities for personal and domestic hygiene. Environmental sanitation comprises both behaviour and facilities to form a hygienic environment.

The water supply and sanitation provide the necessary barrier between the pollutants, natural - built environment and humans. The waste and resource sub-systems of water and environmental sanitation (yellow); the natural environment (blue); the built environment (orange).
1.3 Waste Products

Brown water is the mixture of faeces, anal cleansing water (if anal cleansing is practised) and flushing water. Blackwater is the mixture of urine with brown water.
Greywater is used water generated through bathing, hand-washing, cooking or laundry. It is sometimes mixed or treated along with blackwater.

Faecal sludge is the general term for the undigested or partially digested slurry or solid resulting from the storage or treatment of blackwater or excreta. Septage is well digested and blackish slurry or solids which needs lesser treatment than faecal sludge. Sewage sludge is usually generated during aerobic treatment of domestic wastewater at the sewage treatment plants.

<table>
<thead>
<tr>
<th>Characterizing wastewater</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Solids</strong></td>
</tr>
<tr>
<td>• TS: Total Solids &amp; TSS: Total Suspended Solids</td>
</tr>
<tr>
<td>• Suspended solids- bigger than 0.2Um</td>
</tr>
<tr>
<td>• Settleable and colloidal solids</td>
</tr>
<tr>
<td>• 70% organic solids; 30% inorganic solids</td>
</tr>
</tbody>
</table>

Turbidity and organic solids deplete the oxygen in the water body and prevent light from penetrating.

<table>
<thead>
<tr>
<th>Organic Constituents</th>
</tr>
</thead>
<tbody>
<tr>
<td>• BOD: Biological Oxygen Demand</td>
</tr>
<tr>
<td>• COD: Chemical Oxygen Demand</td>
</tr>
<tr>
<td>• Biodegradable organics: proteins, carbohydrates and fats.</td>
</tr>
<tr>
<td>• BOD signifies approximate amount of oxygen required to stabilise the organic matter.</td>
</tr>
</tbody>
</table>

Used to design treatment units, measure efficiency of the processes, evaluate compliance with the discharge standards.

Total suspended solids are those solids that do not pass through 0.2-um filter. About 70% of those solids are organic and 30% are inorganic. The inorganic fraction is mostly sand and grit that settles to form an inorganic sludge layer. Total suspended solids comprise both settleable solids and colloidal solids. Settleable solids will settle in an Imhoff cone within one hour, while colloidal solids (which are not dissolved) will not settle in this period. Suspended solids are easily removed through settling and/or filtration. However, if untreated wastewater with a high suspended solids content is discharged into the environment, turbidity and the organic content of the solids can deplete oxygen from the receiving water body and prevent light from penetrating.

Biodegradable organics are composed mainly of proteins, carbohydrates and fats. If discharged untreated into the environment, their biological stabilisation can lead to the depletion of natural oxygen and development of septic conditions. BOD test results can be used to assess the approximate quantity of oxygen required for biological stabilisation of the organic matter present, which in turn, can be used to determine the size of wastewater treatment facilities, to measure the efficiency of some treatment processes and to evaluate compliance with wastewater discharge permits.
Nitrogen and phosphorus, also known as nutrients or bio stimulants, are essential for the growth of microorganisms, plants and animals. When discharged into the aquatic environment, these nutrients can lead to the growth of undesirable aquatic life, which rob the water of dissolved oxygen. When discharged in excessive amounts on land, they can also lead to groundwater pollution.

Communicable diseases can be transmitted by pathogenic organisms present in wastewater. The presence of specific monitoring organisms is tested to gauge plant operation and the potential for reuse.

Coliform bacteria include genera that originate in faeces (e.g. Escherichia) as well as genera not of faecal origin (e.g. Enterobacter, Klebsiella, Citrobacter). The assay is intended to be an indicator of faecal contamination; more specifically of E. coli which is an indicator microorganism for other pathogens that may be present in faeces. Presence of faecal coliforms in water may not be directly harmful and does not necessarily indicate the presence of faeces.

</table>
The figure shows the sources of waste in the household and neighbourhood (green) and the waste and resource flows (brown). All waste and resource flow require an integrated management (green) within a settlement: regulatory system and its enforcement, as well as operation and maintenance for safe transport, treatment, safe disposal, and/or reuse (blue). What needs to change is our thoughts. We should regard waste as resources to develop an integrated viewpoint. In India we call a wastewater treatment facility as STP, however in Singapore where fresh water is very limited, they call it water reclamation facility.

1.4 EcoSan

EcoSan – Ecological Sanitation

Hygienically safe, economical and closed loop system
Ecological sanitation commonly known as Ecosan has three fundamental aspects – (a) rendering human excreta safe, (b) preventing pollution rather than attempting to control it after we pollute, and (c) using the safe products of sanitized human excreta for agricultural purposes. This approach fits in the definition of circular economy and can be characterized as “Sanitize-and-recycle”.

By treating and recycling the waste such as human excreta, pollution of the water cycle is avoided. Thus, the Ecosan concept goes a long way in contributing to sustaining environmental health.

**Objectives**

- Resource recovery and reuse.
- Minimizing the consumption of non-renewable resource.

*Hygienically safe, economical and closed loop system!*

- Ecosan – is not just a toilet interface!
- The concept of EcoSan is resource recovery and reuse oriented.
- It is a concept that is characterized by the desire to safely close the loop.
Greywater is a reflection of household activities, its main characteristics strongly depend on factors such as cultural habits, living standard, household demography, type of household chemicals used etc. Greywater is the least contaminated type of wastewater which needs very less degree of treatment.

The concentration of nutrients in the excreted urine depends on the nutrient and liquid intake, the level of personal activity and climatic conditions. In its pure form, it is sterile and quite rich in nutrients.

From a risk perspective, exposure to untreated faeces is always considered unsafe on account of the high levels of pathogens whose prevalence is dependent on the given population.

### Defects in Conventional Offsite Sanitation System

- Inequitable distribution and use of water resources such as ground and surface water.
- Providing access to sanitation in rapidly urbanizing city is challenging.
- Part of the domestic wastewater is captured and part of the collected wastewater is treated up to the discharge standards.
- Untreated wastewater finds its way into the nearby water body or contaminate the groundwater.
- Overuse of inorganic fertilizers lead to depleting reserves of nutrients.

*Does not follow concept of Environmental Sanitation and negatively impacts the Environmental Health!*

---

Part A: Presentation Slides 15
The conventional offsite sanitation systems is mainly dependent on sourcing raw water from surface water body. The deficit demand is met through groundwater. However, in absence of appropriate regulations and their enforcement, this often leads to inequitable distribution and use of water. Implementing the off site sanitation system in a rapidly urbanizing city is a challenge. The resources such as funds, expertise for design and implementation and human resources etc. required for scaling up of sanitation systems are not available. As a result of which, part of the wastewater is collected and treated and discharged into the surface water bodies, while large quantity of wastewater goes untreated. This leads to pollution of water resources.

To feed the residents of the city, the agriculture mainly depends on the inorganic fertilizers which are extracted from natural resources. Over use of these inorganic fertilizers not only depletes the reserves but also lead to greater pollution through agriculture runoff.

Defects in conventional off-site sanitation system:

- Inequitable distribution and use of resources such as groundwater.
- Providing access to sanitation in rapidly urbanizing city is challenging.
- Part of the domestic wastewater is captured and part of the collected wastewater is treated up to the discharge standards.
- Overuse of inorganic fertilizer leads to depleting reserves of nutrients.

Scaling up of Ecosan concept is possible at the city scale. This will not only reduce the dependency on the surface water bodies, but also result into significant decrease on the water pollution. The concept promotes segregation of waste streams such as black water, urine and grey water. The nutrients from the black water and urine can be recovered through treatment processes and reused in the agriculture. The grey water can be treated at various levels and reused locally.
Stormwater management can also provide additional sources of water.

- Managing the water resources to maintain the environmental flow in the rivers.
- Appropriately managing the waste resources at the source, the energy and nutrients can be recovered and recycled.
- Prioritization of reuse of treatment end-products over disposal.
- Reducing the dependency on the inorganic fertilizers.
- Enforcement on stormwater management to reduce dependency on surface water bodies.

1.5 Urban Challenges

Factors leading to deficiencies in water and sanitation can be found on every level – from local to international. The causes for the inadequacies are thus proximate (household/local), contributory (city & town) or underlying (global/international).
This slide shows the pace at which India has undergone urbanization as compared to other countries in the world. Although, India will have less percentage of population living in the urban centers, it will be a host to many cities having population more than 10 million. The pace at which the urban centers are experiencing population explosion, it is very difficult to provide adequate municipal services such as drinking water, access to toilet and safe management of solid and liquid water. Add to this the population migrating from the rural to urban centers in search of better employment opportunities puts more stress in the infrastructure.
The graph on the left shows that percentage of population residing in the rural areas is decreasing and by 2045 more than 50% of the population in India will be living in urban areas. It is expected that in less than a decade’s time, India will have seven cities with more than 1 crore population and 62 and 70 cities with population between 10 to 50 lakh and 5 to 10 lakhs respectively.

### Sanitation planning

- Cities are engines of economic & social development
- Urban development relies on good infrastructure and reliable service provision
- Sanitation systems are only considered partially!
- Inadequate & unachievable regulations, lead to choice of unsustainable solutions.
- Failures or unsustainable solutions put huge financial burden on ULBs.

### Programs

#### Swachh Bharat Mission (SBM)
- **Objectives**
  - Eliminating open defecation
  - Eliminating manual scavenging
- **To ensure that**
  - No HH engages in OD
  - No new insanitary toilets are constructed
  - Pit latrines are converted into sanitary toilets
- **Components**
  - IHHT | Community Toilets | Public Toilets

#### Atal Mission for Rejuvenation and Urban Transformation (AMRUT)
- **Objectives**
  - Providing Basic Services (e.g. Water Supply, Sewerage, Septage Management, Urban transport) in the city
- **To ensure that**
  - Every household has access to a tap with the assured supply of water and a sewerage connection.
- **Components**
  - Water Supply | Sewerage | FSSM
Swachh Bharat Mission (SBM) has launched in the year 2014 to eliminate open defecation and improve solid waste management. In first phase, it has aimed to achieve 100% ODF status for Urban and Rural areas by 2nd Oct 2019. The objectives of the first phase of the mission also included eradication of manual scavenging, generating awareness and bringing about a behaviour change regarding sanitation practices, and augmentation of capacity at the local level. The second phase of the mission (SBM 2.0) aims to sustain the open defecation free status and improve the management of solid and liquid waste. The mission is aimed at progressing towards target 6.2 of the Sustainable Development Goals (SDGs) established by the United Nations in 2015. Under SBM 2.0 urban, there are different guidelines has published for the urban local bodies which covers the protocols to sustain the status of ODF of the cities by ensuring proper maintenance of the sanitation facilities, hereby referred to as SBM ODF+, and safe collection, conveyance, treatment and disposal of all faecal sludge and sewage, hereby referred to as SBM ODF++.

The Atal Mission for Rejuvenation and Urban Transformation (AMRUT) mission has initiated in June 2015 which aimed to provide the basic utility services (e.g. water supply, sewerage, septage management, urban transport) to households and build amenities in cities which will improve the quality of life for all. The purpose of Atal Mission for Rejuvenation and Urban Transformation (AMRUT) is to ensure that every household has access to a tap with the assured supply of water and a sewerage connection, to increase the amenity value of cities by developing greenery and well-maintained open spaces (e.g. parks) and to reduce pollution by switching to public transport or constructing facilities for non-motorized transport (e.g. walking and cycling). All these outcomes are valued by citizens, particularly women, and indicators and standards have been prescribed by the Ministry of Housing and Urban Affairs (MoHUA) in the form of Service Level Benchmarks (SLBs).

Smart City Mission has initiated in June 2015 and aimed to promote cities that provide core infrastructure and give a decent quality of life to its citizens, a clean and sustainable environment and application of Smart Solutions. The focus is on sustainable and inclusive development and the idea is to look at compact areas, create a replicable model which will act like a lighthouse to other aspiring cities. The core infrastructure elements in a Smart City would include adequate water supply, assured electricity supply, sanitation, including solid waste management, efficient urban mobility and public transport, affordable housing, especially for the poor, robust IT connectivity and digitalization, good governance, especially e-Governance and citizen participation, sustainable environment, safety and security of citizens, particularly women, children and the elderly, and health and education.

Jal Jeevan Mission is the new initiative of Ministry of Jal Shakti since 2019 which focuses on rural areas. Its objectives are,

• To provide functional tap connections (FHTC) to every rural household.
• To prioritize provision of FHTCs in quality affected areas, villages in drought prone and desert areas, Sansad Adarsh Gram Yojana (SAGY) villages, etc.
• To provide functional tap connection to Schools, Anganwadi centres, GP buildings, Health centres, wellness centres and community buildings
• To monitor functionality of tap connections.
• To promote and ensure voluntary ownership among local community by way of contribution in cash, kind and/or labour and voluntary labour (shramdaan)
• To assist in ensuring sustainability of water supply system, i.e. water source, water supply infrastructure, and funds for regular O&M
• To empower and develop human resource in the sector such that the demands of construction, plumbing, electrical, water quality management, water treatment, catchment protection, O&M, etc. are taken care of in short and long term
• To bring awareness on various aspects and significance of safe drinking water and involvement of stakeholders in manner that make water everyone’s business

National Faecal Sludge and Septage Management (FSSM) Policy has released in 2017 to set the context, priorities, and direction for and to facilitate, nationwide implementation of FSSM services in all ULBs such that there will be safe and sustainable sanitation approach at city level. The key objective of the policy is to mainstream the FSSM in urban India by 2019 and ensure that the all benefits of wide access to safe sanitation accrue to all citizens across the sanitation value chain with containment, extraction, transportation, treatment, and disposal / re-use of all faecal sludge, septage and other liquid waste and their by-products and end-products. Another objective of the policy is to enable and support synergies among relevant Central Government programs such as SBM, AMRUT and the Smart Cities Mission to realise safe and sustainable sanitation for all. Even, FSSM policy expects to mitigate gender-based sanitation insecurity directly related to FSSM, reducing the experience of health burdens, structural violence, and promote involvement of both genders in the planning for and design of sanitation infrastructure.

- Cities, as engines of economic growth and social development, require large quantities of natural resources to meet the inhabitants’ economic and social needs. Good infrastructure and reliable service provision are keys to a sustained urban development.
- To respond to the lack of sanitation infrastructure affecting especially the urban poor, many governments, development agencies and NGOs have launched programmes to provide the poor and vulnerable population with sanitation options.
- The sanitation systems are often only considered partially. For example, on-site based sanitation solutions (latrine or septic tank-based) frequently do not include excreta and faecal sludge emptying, transport or treatment services and facilities.
- Additionally, local business opportunities, as well as demand and potential use of waste resources, such as water, nitrogen or bio solids, are given little attention.
- Failures or unsustainable solutions put huge financial burden on municipalities.

### Challenges at city level

<table>
<thead>
<tr>

</table>

<table>
<thead>
<tr>
<th>• Illegal settlements</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Inadequate water and sanitation provision</td>
</tr>
<tr>
<td>• From illegal to legal</td>
</tr>
</tbody>
</table>

The WHO/UNICEF Assessment identified cost recovery and inadequate operation and maintenance as two of the main constraints on the development of water supply and sanitation – both largely a consequence of the weakness or incapacity of water and sanitation agencies.

The spatial distribution of the population has always been a key factor on the policy agenda of governments. The governments of developing countries have often expressed concern about their inability to provide basic services for their rapidly growing urban populations, including safe drinking water, sanitation, affordable housing, and public transport.
Challenges faced by small cities

- Small cities (<5,00,000 inhabitants). India has more than 400 cities!
- Small cities are neither urban nor rural.
- Most affected by population growth and urbanisation.

Small-city problems (< 500,000):
- Weak governments.
- No official water and sanitation utilities/institutions.
- No professional staff.
- Neglected by governments and donors.

The management gap occurs because the large towns are not big enough to make top down/centralization approach economical or bottom up/decentralization approach manageable due to lack of resources.

Summary

- To maintain clean and healthy natural environment by managing built environment properly through environmental sanitation services.

- Environmental Sanitation consists of proper management of human excreta and wastewater.

- Ecological sanitation introduces the concept of water and nutrient resource management for closing loop at local level for ensuring sustainability.

- Urban challenges in sanitation planning constitute of different aspects, however are mainly driven by lack of professional capacity and management gap.
Session 02

Sanitation Systems
2. Sanitation Systems

Learning objectives

• To have in-depth knowledge of sanitation systems and suitability of different types of sanitation systems.

• To understand functional groups in sanitation systems and specific objective of each functional group.

• To understand options for each functional group and their inter linkages.

• Case studies on reuse of treated end products in sanitation systems.

In this session we will introduce the concept of sanitation systems. This will enable them to look at complete process of liquid waste management- from generation to disposal. We are also introducing the participants to the types if sanitation systems, thereby familiarizing them with the most prevalent type of sanitation system being used in India. The session continues to focus on types of sanitation system around us.

Contents

Sanitation Systems

• Objectives
• Types

Functional Groups
• User interface
• Containment unit
• Conveyance
• Treatment
• Reuse or disposal

Case Studies
• Reuse of treated end products in sanitation system
A sanitation system is comprised of Products (wastes) that travel through Functional Groups which contain Technologies that can be selected according to the context. By selecting a Technology for each Product from each applicable Functional Group, one can design a logical Sanitation System.

A sanitation system also includes the management, operation and maintenance (O&M) required to ensure that the system functions safely and sustainably.

**Definition & Objectives**

It is a multi-step process in which human excreta and wastewater are managed from the point of generation to the point of use or ultimate disposal with minimal human intervention.

**OBJECTIVES**

- Protect and promote health
- Protect the environment
- Be simple in technology
- Be affordable
- Be culturally acceptable
- Work for everyone
In the urban centres of the developing countries, due to availability of the water, use of flush toilets and the myth that wet systems are the easiest to operate and maintain, water borne systems are used. Water is used to transport the waste from one point to another. These systems are called wet systems. The wet systems can be classified into two types depending on where the treatment of waste is done. In case of “Off Site” disposal, the liquid and solids are carried away from the point of generation using sewerage network. The sewerage network brings the waste from all the households to one point where a wastewater treatment plant is set up. This type of system is called as sewered sanitation.

In case of “On Site” disposal, the solids are stored in the containment unit and the liquid effluent is disposed off into the ground using soak pits or soak away. After a duration of few years, the contained solids are emptied and transported for further treatment. Since this conveyance of solids is done by mechanised equipment such as vacuum trucks, this type of sanitation system is called as non sewered sanitation.

However, in India, we have developed a hybrid system where in the solids are contained in the septic tank at the household level and the sullage is disposed off into the drains outside the houses. The network of drains thus collects the sullage from all the households and by gravity brings it to the surface water body such as rivers, lakes and ponds. The septage from the septic tank is emptied after few years and transported by vacuum trucks for either treatment or direct disposal. Since a network of drains is involved for conveyance of the sullage, these systems cannot be classified as completely sewered or non sewered sanitation system.
Dry sanitation is defined as the disposal of human waste without the use of water as a carrier and the by-products i.e. decomposed solids and urine are then used as fertilizer.

Urine diversion toilets where faeces, urine and anal cleansing water segregated separately at source. A urine-diverting dry toilet (UDDT) is a toilet that operates without water and has a divider or three-hole pan so that the user, with little effort, can divert the urine away from the faeces. The effectiveness of faeces management in most UDDTs relies on the faecal material remaining as dry as possible in the vault.
Urine diversion dehydration toilet

- Does not require water for flushing
- Most appropriate for rural and farming families
- End products
  - Urine as liquid fertilizer after hygenization
  - Humanure as soil conditioner
- Can be constructed with locally available materials – bricks, mortar etc.
- Relatively high capital cost

- Does not require a constant source of water
- No real problems with odors and vectors (flies) if used and maintained correctly (i.e., kept dry)
- Can be built and repaired with locally available materials
- Low capital and operation costs
- Suitable for all types of users (sitters, squatters, washers, wipers)

It does not require a constant source of water. There are no real problems with odour and vectors (flies) if used and maintained correctly (i.e. kept dry). It can be built and repaired with locally available materials which indirectly effects in low capital and operation costs. These are suitable for all types of users(sitters, squatters, washers, wipers).
The tiger toilet is a pour-flush pit latrine toilet that uses vermifiltration to treat waste. The vermifiltration technology uses earthworms or tiger worms to decompose the waste from latrines rapidly into vermi-compost, while liquids drain out of the system. It consists of a strong and durable toilet room and the Tiger biodigester attached to it. The system needs minimal maintenance and offers users a flush-and-forget experience.

2.2 Functional Groups

Various technologies which perform the same or similar type of function are called as Functional
Groups. When different technologies from different functional groups are clubbed together, a sanitation system is made. Careful selection of the technologies needs to be done to make the sanitation system functional. A sanitation system should consider all the products generated and all the Functional Groups these products are subjected to prior to being suitably disposed of. Domestic products mainly run through five different Functional Groups, which form together a system.

A sanitation system consists of five different components as shown in the slide- User Interface, Containment Unit, Conveyance Unit, Treatment Unit and Disposal or Reuse. A sanitation system can be formed using three or more components. The options available under each component is listed in the boxes on the slide. We will be looking into different sanitation systems which will make the picture clearer as to how each component connects with other.
User interface refers to the unit where the waste products are introduced into the sanitation system. Typically, it consists of different types of sanitary fixture in the toilet such as toilet, urinal or even a washbasin. Usually in wet sanitation systems, user interface is the place, where the waste comes in contact with water for the first time. Depending upon the type of the interface and the amount of water mixed, the final composition and characteristic of the waste is determined. Choice of user interface is often perceived to be cost driven, however, lately due to increasing scarcity of drinking water, availability of water also determines the choice of user interface.

User interface describes the type of toilet, pedestal, pan or urinal the user comes in contact with. User interface also determines the final composition of the product, as it is the place where water is introduced in the system. Thus, the choice of user interface is often dependent on the availability of water.
The technologies which are used for the collection and storage of the products generated at the user interface. In the case of extended storage, some treatment may be provided, though it is generally minimal and dependent on storage time. All the units have to be either connected to conveyance or use/disposal function group for liquid effluent and to conveyance to solids. All the units need to be emptied regularly (depending on the design criteria) for solids. These solids in turn need to be treated or processed before use/disposal.
Conveyance describes the way in which products are moved from one process to another. Although products may need to be moved in various ways to reach the required process, the longest and most important gap lies between on-site storage and (semi-) centralised treatment. For the sake of simplicity, conveyance is thus limited to moving products at this point.

**Conveyance**

- The way in which products are moved from one point to another.
- Conveyance can be gravity or energy driven.
- The longest and most important gap lies between user interface and treatment stage.
- Products may need to be moved in various ways to reach the required process, ex. Sewage Pumping Stations.
Based on the level of liquid waste management, the treatment stage is classified as centralized or decentralized treatment plant. Centralized treatment plant needs a conveyance unit which collects the wastewater and bring it offsite at one point for treatment. In case of decentralized treatment plant, conveyance unit is optional. Based on type of the treatment technology, the requirement of expertise and skills vary. However, it is safe to say that without operation and maintenance by skilled and appropriately trained person, any treatment technology is bound to fail.

The technical and physical criteria for choosing appropriate technology for treatment are as follows: 1. Climate, 2. Availability of space, 3. Ground condition, 4. Ground water level and contamination. There are two different types of treatment systems i.e. mechanised or non-mechanised. These treatment systems are depended on physical, biological, chemical or photolytic treatment processes.
There are different types of treatment technologies which can be implemented at various levels of wastewater management. The choice of technology depends on different criteria. Session 17 is dedicated to discussing the treatment technologies and their working in detail.

(Semi-) centralised treatment refers to the treatment systems which, unlike those used on-site, are larger, require a greater inflow (that can usually not be met by just one family) and often more skilled operation.

**Use and/or disposal**

- The ways in which products are ultimately returned to the soil or water, either as harmless substances or useful resources.
- Products can also be re-introduced into the system as new products.
- **End Products** - Dehydrated faeces, Sterilized urine, Treated wastewater, Bio solids
Use and/or disposal refers to the ways in which products are ultimately returned to the soil, either as harmless substances or useful resources. Furthermore, products can also be re-introduced into the system as new products. A typical example is the use of partially treated greywater used for toilet flushing.

### Use and/or disposal

- **Agriculture**
  - The dried faecal matter is used as soil conditioner in agriculture. The soil conditioner improves the texture of the soil and helps to increase the moisture retention capacity of the soil. The sterile urine after disinfection is used as fertilizer in the agriculture. Urine as a liquid fertilizer contains high amount of nitrates and phosphates which can reduce the consumption of inorganic fertilizers.

- **Aquaculture**
  - The term aquaculture refers to the controlled cultivation of aquatic plants and animals by making use of various types of wastewater as a source for nutrients and/or warm temperatures for plants and fish to grow. Fish can be grown in ponds that receive effluent or sludge where they can feed on algae and other organisms that grow in the nutrient-rich water. The fish, thereby, remove the nutrients from the wastewater and are eventually harvested for consumption. You can also read the description of plant aquacultures.

- **Recharge or disposal**
  - This can be done in several ways. The most common way is to have a leach field of soak pit. However there are other ways like soil aquifer treatment, short crop rotation which are popular in other countries and utilize the treated wastewater in most sophisticated way.

- **Energy products from sludge**
  - The sludge can be processed to make solid or liquid fuel depending on treatment process used. The biogas generated through anaerobic digestion can be directly used as liquid fuel or alternatively converted into electricity. Dried sludge can also be used as solid fuel in furnaces or brick kiln due to its high calorific value.

As per Environment Protection Act and Rules, 1986 and Amendments, 2017, the effluent discharge standards shown in the table has to be followed for the disposal or reuse of the wastewater after treatment in sewage treatment plants in India.

The primary criteria is that the treatment facility should be able to produce end products meeting
the standards of discharge/ enduse. Currently there are standards for the wastewater which have been adopted for the treated liquid fraction for STPs or FSTPs. However, there are not standards laid down for bio solids in STPs and FSTPs. Hence, the primer and the National FSSM policy recommend to follow US EPA standard or WHO standards.

The 2006, World Health Organisation's (WHO) Guidelines for the safe use of wastewater, biosolids and greywater maximises the public health protection and the beneficial use of important resources. These guidelines provide a comprehensive framework for managing health risks associated with the use of human wastes in agriculture and aquaculture.

Use of wastewater is becoming increasingly attractive to policy makers and water users in the face of increasing water scarcity and competing demands for water. Peri-urban agricultural and aquaculture using wastewater also has many market advantages. In addition to being a reliable year-round water supply, wastewater also contains valuable nutrients that can increase crops yields and save on artificial fertilizers and alternative water sources. However, expanding formal reuse is typically complicated by weak coordination, complexity in the inter-operability of policies and regulations for reuse, and difficulties in identifying and managing the real and perceived health risks associated with reuse.

2.3 Case Studies
The East Calcutta Wetlands are a complex of natural and human-made wetlands lying east of the city in West Bengal. The wetlands cover 125 square kilometers and include salt marshes and salt meadows, as well as sewage farms and settling ponds. The wetlands are used to treat Kolkata’s sewage, and the nutrients contained in the wastewater sustaining fish farms and agriculture. Wastewater will pass through a water hyacinth tank where some amount of heavy metals and suspended solids may be absorbed from the wastewater before this water is allowed to enter into the fish ponds the process is called RHIZOFILTRATION.
STP along with secondary and tertiary treatment to be constructed, operated and maintained by MAHAGENCO as per their requirements.

- Grant of Rs. 90 Cr received from JnNURM by NMC shall be passed on to MAHAGENCO towards construction.
- Land required for the project shall be provided by NMC.
- NMC shall supply 110 MLD (+10%) sewage to MAHAGENCO @ Rs 15 Cr / year.

MAHAGENCO has MoU with NMC in support of NMCs Water Reuse Planning and to supply treated wastewater from NMC STP as water linkage to meet additional demand of proposed expansion plan at TPS at Koradi. MoU includes construction of 110 MLD STP with 10% overloading capacity for supplying treated sewage water from the STP to meet the water demand. This is an EPC
Contract which also includes Comprehensive Operation & Maintenance of the Sewage Treatment Plant for the period of ten years.

**Cost of Delivered Water:**
- Capital Cost of the Project (130MLD): Rs. 180 Cr
  - JnNURM Grant: Rs. 90 Cr
  - MAHA GENCO Share: Rs. 90 Cr
- Operation and Maintenance Cost: Rs. 1.50 Cr/Year
- Payment to NMC for raw sewage purchase: Rs. 15 Cr/Year
- Cost of water to MAHAGENCO: Rs. 3.40 per Cum.
- Cost of fresh water from irrigation department: Rs. 1.20 to 9.60 per Cum.

- Ecosan Toilets - Urine Dehydration Dry Toilet (UDDT)
- East Kolkata Wetland
- Bhandewadi STP Nagpur

---

**Summary**

- The main objective of sanitation system is to protect environmental health.

- Choice of sanitation system depends on the affordability and availability of water.

- There are five functional groups in sanitation systems.

- The appropriate sanitation system consists from 2 to 5 functional groups.

- The type of user interface decides the succeeding functional groups.
Session 03

Sanitation Technologies
3. Sanitation Technologies

Learning objectives

- To know the flow of products in Wet Sanitation System further and its types in detail.
- To understand the functional groups involved in wet sanitation system.
- To know the working of functional group – User Interface, Containment unit, Conveyance unit and collection and transport.

In this session we are introducing the participants to the to various technological options for various stages of IWSM and FSSM Service chain – Containment unit, Desludging equipment and conveyance, collection and transport.

- Collection and transport
- Conveyance unit
In the urban centres of the developing countries, due to availability of the water, use of flush toilets and the myth that wet systems are the easiest to operate and maintain, water borne systems are used. Water is used to transport the waste from one point to another. These systems are called wet systems. The wet systems can be classified into two types depending on where the treatment of waste is done. In case of “Off-site” disposal, the liquid and solids are carried away from the point of generation using sewerage network. The sewerage network brings the waste from all the households to one point where a wastewater treatment plant is set up. This type of system is called as sewered sanitation.
In the case of “On-site” disposal, the solids are stored in the containment unit and the liquid effluent is disposed off into the ground using soak pits or soak away. After a duration of a few years, the contained solids are emptied and transported for further treatment. Since this conveyance of solids is done by mechanised equipment such as vacuum trucks, this type of sanitation system is called as non sewered sanitation.

However, in India, we have developed a hybrid system where in the solids are contained in the septic tank at the household level and the sullage is disposed off into the drains outside the houses. The network of drains thus collects the sullage from all the households and by gravity brings it to the surface water body such as rivers, lakes and ponds. The septage from the septic tank is emptied after few years and transported by vacuum trucks for either treatment or direct disposal. Since a network of drains is involved for conveyance of the sullage, these systems cannot be classified as completely sewered or non sewered sanitation system.

A sanitation system consists of five different components as shown in the slide- User Interface, Containment Unit, Conveyance Unit, Treatment Unit and Disposal or Reuse. A sanitation system can be formed using three or more components. The options available under each component is listed in the boxes on the slide. We will be looking into different sanitation systems which will make the picture clearer as to how each component connects with other.
3.2 Functional Groups

User interface describes the type of toilet, pedestal, pan or urinal the user comes in contact with. User interface also determines the final composition of the product, as it is the place where water is introduced in the system. Thus, the choice of user interface is often dependent on the availability of water. i) The type of toilet, pedestal, pan or urinal the user comes in contact with ii) It is the place where water is introduced in the system iii) Determines the final composition of the product iv) The choice of user interface is often dependent on the availability of water.
### Pour Flush toilet

- Excreta of one user are flushed before the next user arrives.
- Prevents odour.
- Suitable for most users (except for physically challenged).
- Material – Ceramic, plastic, FRP.
- Variants available. (Rural pan, Squatease etc)
- Low capital costs

- The water seal effectively prevents odour.
- The excreta of one user are flushed away before the next user arrives.
- Suitable for all types of users (sitters, squatters, wipers and washers).
- Low capital costs; operating costs depend on the price of water.

### Cistern Flush toilet

- Flush toilet with a cistern.
- Extra plumbing is required.
- Western WC pan is used in toilets for physically challenged.
- Flush uses 8-12 liters of water.
- Low flush toilet uses 4-6 liters of water per flush.

The cistern flush toilet is usually made of porcelain and is a mass-produced, factory-made User Interface. The flush toilet consists of a water tank that supplies the water for flushing the excreta and a bowl into which the excreta are deposited. The attractive feature of the toilet is that it incorporates a sophisticated water seal to prevent odour from coming back up through the plumbing.
Vacuum toilets are flush toilets that use suction for the removal of faeces and urine resulting in a minimal requirement of water (0.5 to 1.5 litres). Vacuum toilets provide the same level of comfort as traditional flush toilets and they help saving costs due to the minimised amount of flush water. Due to the fact that the effluent has a high organic matter content, vacuum toilets are specifically adapted for the use in combination with separate greywater and blackwater treatment; or aerobic digestion treatment for biogas production. Vacuum toilet systems are applicable both in large and small buildings, trains, ships and airplanes.
This technology consists of two alternating pits connected to a pour flush toilet. The blackwater (and in some cases greywater) is collected in the pits and allowed to slowly infiltrate into the surrounding soil. Over time, the solids are sufficiently dewatered and can be manually removed with a shovel and reused on-site, much like compost, to improve soil fertility and fertilise crops. Although most pathogens are filtered during soil infiltration or die-off with time and distance, there remains a risk of groundwater pollution, particularly in densely populated areas or in areas with a high groundwater table.

This consists of two alternating pits connected to a pour flush toilet. The blackwater (and in some cases greywater) is collected in the pits and allowed to slowly infiltrate into the surrounding soil. Over time, the solids are sufficiently dewatered and can be manually removed with a shovel and reused on-site, much like compost, to improve soil fertility and fertilise crops. Although most pathogens are filtered during soil infiltration or die-off with time and distance, there remains a risk of groundwater pollution, particularly in densely populated areas or in areas with a high groundwater table.
A septic tank is a watertight chamber made of brick work, concrete, fibreglass, PVC or plastic, through which blackwater from cistern or pour-flush toilets and greywater through a pipe from inside a building or an outside toilet flows for primary treatment. Settling and anaerobic processes reduce solids and organics, but the treatment is only moderate. Effluent is infiltrated into the ground or transported via a sewer to a (semi-)centralised treatment plant. Accumulating faecal sludge needs to be dug out the chamber regularly and correctly disposed of.

Further reading: http://www.sswm.info/category/implementation-tools/wastewater-treatment/hardware/site-storage-and-treatments/septic-tank
Vacuum truck is a most sophisticated equipment which is widely used for desludging of containment systems such as septic tanks. The vacuum trucks come in different sizes and types. As shown in picture trailer mounted tank fitted with vacuum pump is the most basic form of equipment. In this case, the trailer can be tugged with tractor and the vacuum pump is operated using diesel run motor. An improved version is a truck mounted tank fitted with the vacuum pump. In this case there is possibility that the vacuum pump can be coupled with the drive train of the truck, thus eliminating the need of separate diesel run motor. Now-a-days, vacuum trucks fitted with jetting equipment is also available for cleaning sewerage network and manholes.
Vacutug is a smaller version of the trailer mounted type of vacuum truck. The need of such a smaller size desludging equipment arises from the fact that not all the containment units are easy to access. Especially in the unorganized settlements such as urban slums, the access roads are small and a vacuum truck cannot be driven to the household. Hence, vacutug is used to empty the content of the septic tank in batches and empty it into the bigger truck. The tugs can be as small as 300 KL. The most important thing while making a vacutug is to keep in mind that it should be easy enough to pull it by persons or vehicle.
The products generated at the User Interface or onsite Collection and Storage/Treatment technology by removing and/or transporting them to a subsequent offsite (Semi-) Centralized Treatment, Use and/or Disposal technology. They are sewer-based technologies.

**Gravity Sewers**

- Designed to handle all types of wastewater containing solids.
- Separate sewers carry domestic sewage and storm water.
- Designed for attaining cleansing velocity in pipes.
- The laying of sewers is done by ULB.
- House connection charged to be paid by household.

Conventional gravity sewers are large networks of underground pipes that convey blackwater, greywater and, in many cases, stormwater from individual households to a (Semi-) Centralized Treatment facility, using gravity (and pumps when necessary).

The conventional gravity sewer system is designed with many branches. Typically, the network is subdivided into primary (main sewer lines along main roads), secondary and tertiary networks (networks at the neighborhood and household level).
A solids-free sewer is a network of small-diameter pipes that transports pre treated and solids-free wastewater (such as Septic Tank effluent). It can be installed at a shallow depth and does not require a minimum wastewater flow or slope to function.

Solids-free sewers are also referred to as settled, smallbore, variable-grade gravity, or septic tank effluent gravity sewers. A precondition for solids-free sewers is efficient primary treatment at the household level. An interceptor, typically a single-chamber Septic Tank, captures settleable particles that could clog small pipes. The solids interceptor also functions to attenuate peak discharges. Because there is little risk of depositions and clogging, solids-free sewers do not have to be self-cleansing, i.e., no minimum flow velocity or tractive tension is needed. They require few inspection points, can have inflective gradients (i.e., negative slopes) and follow the topography. When the sewer roughly follows the ground contours, the flow is allowed to vary between open channel and pressure (full-bore) flow.
Solid Free Sewer

**Decentralised Sanitation System**

- **Commerical Properties**
  - Organic load: low
  - Hydraulic load: high

- **Residential Properties**
  - Organic load: low
  - Hydraulic load: less

**Solid Free Sewers**
- Planning and execution is relatively easy.
- More properties per unit distance
- Less water for cleansing pipes
- Less O&M

Smaller Gradient
Covers more spatial area w/o requiring pumping station

Simplified Sewer

- Appropriate for densely populated areas with low availability of area.
- Is laid at shallower depths with cleanout points.
- Lowest capital cost as compared to other sewers.
- Needs frequent O&M in the form of cleaning clogs and flushing.
A simplified sewer describes a sewerage network that is constructed using smaller diameter pipes laid at a shallower depth and at a flatter gradient than Conventional Sewers. The simplified sewer allows for a more flexible design at lower costs.

Conceptually, simplified sewerage is the same as Conventional Gravity Sewerage, but without unnecessarily conservative design standards and with design features that are better adapted to the local situation. The pipes are usually laid within the property boundaries, through either the back or front yards, rather than beneath the central road, allowing for fewer and shorter pipes. Because simplified sewers are typically installed within the condominium, they are often referred to as condominial sewers. The pipes can also be routed in access ways, which are too narrow for heavy traffic, or underneath pavements (sidewalks). Since simplified sewers are installed where they are not subjected to heavy traffic loads, they can be laid at a shallow depth and little excavation is required.

### Summary

- In India, hybrid sanitation system is mostly followed; wherein the septic tank effluent along with the grey water is discarded by the household.

- Solid free sewer is appropriate collection and conveyance system for sullage.

- Regular emptying of septic tank is necessary for proper functioning of solid free sewers.

Session 05

Liquid Waste Management
5. **Liquid Waste Management**

**Learning objectives**

- To understand different levels of liquid waste management with respect to changing urban settings.
- To look in detail into different aspects of centralized and decentralized liquid waste management.
- To understand tools and different aspects of planning of liquid waste management.

**Contents**

- Levels of Wastewater Management
- Centralized Wastewater Management
- Decentralized Wastewater Management
- Planning of Sanitation Systems
5.1 Liquid Waste Management

There are different levels in liquid waste management. There are few factors which we have to consider while planning the wastewater management. The factors are like population density, the type of housing, availability of space or land for development of utility infrastructure such as sewerage lines or treatment plants and affordability of the environmental services by the local administration. Liquid waste management has two approaches centralised systems or decentralised systems.
In centralised system approach, it is very crucial to understand the level or type of habitat while planning liquid waste management. There are different levels or types of habitat like URBAN, PERI-URBAN, RURBAN or RURAL. In the first part we will understand the URBAN habitat which has the very high population density and has areas with high rise buildings. Generally, urban administrations and urban population have high affordability of implementing and maintaining these environmental services but there is problem of lack of space or land for development of utility infrastructure. In URBAN case, it has suitability of centralised system i.e. household connections with sewerage system and wastewater transferred in centralised treatment system which further disposed of into the surface water bodies after treatment.
In the case of PERI-URBAN habitat, which generally has the high or medium population density and has areas with high rise buildings. Generally, local administration and local people have affordability of developing and maintaining the environmental services. In PERI-URBAN case, it has suitability of decentralised system i.e. household have individual household toilets and on-site septic tanks which can be connected with sub lines (no sewage pumping stations) and wastewater is collected at decentralised treatment system by gravity. Further, it can be disposed into the surface water bodies after treatment or reused for irrigation.

In the case of RURBAN habitat, which generally has the scattered housing with medium or low population density and has areas with 2-3 story buildings. Generally, local administration and local people have less affordability for developing and maintaining the environmental services. In RURBAN case, it has suitability of clustered or regional approach for wastewater management system i.e. household have individual household toilets (IHHT) and septic tanks which can be connected with solid free sewers and wastewater is collected at clustered based wastewater treatment systems by gravity. Further, it can be disposed off into the surface water bodies after treatment or reused for irrigation or other non-potable purposes.
In the case of RURAL habitat, which generally has the scattered hamlets with low population density and has areas with 1-2 story buildings. Generally, local administration and local people have very less affordability for developing and maintaining the environmental services. In RURAL case, it has on-site sanitation system i.e. household have individual household toilets and septic tanks / soak pits and has segregation of black water and grey water. Generally, the disposal happens using leach pits or soak away zones. In this case, the wastewater management at individual household level with primary treatment. Some cases, toilets are connected with biogas systems which are in farmland premises or household premises.

5.2 Centralised Wastewater Management
Centralised system should have water driven infrastructure where excreta or solids are mixed with water to facilitate conveyance to the wastewater treatment systems. As per CPHEEO, the water consumption is considered as 135 lpcd in urban which is important while designing the wastewater treatment system. In treatment system, liquid and solids are separated and treated water is disposed off/reused.

**Characteristics**

- Water driven infrastructure for solids - excreta
- The water consumption- 135 LPCD
- Objective of designing sewerage network – no deposition of solids
- Treatment plant – to separate solids and liquids

**Requirements**

- All the properties to have flush toilets with sewerage connections
- Sewerage network with sewage pumping stations for collecting and conveying the wastewater
- Centralized treatment plant with mechanization and sophisticated control systems
- Disposal point large enough to accommodate daily load of organic constituents and nutrients.
In centralized system the following components has to be present:

- The individual household toilets have to be flush toilet with the sewerage connections,
- The sewerage network with sewer pumping stations for collecting and conveying the wastewater from the households,
- The sewage treatment plant (STP) with mechanization and appropriate control system,
- A suitable disposal point where the treated water can be disposed. In absence of disposal point, an appropriate reuse infrastructure should be available.

Centralized system consists of: i) Centralized collection system (sewers) that collects wastewater from many wastewater producers: households, commercial areas, industrial plants and institutions, and transports it to ii) Centralized wastewater treatment plant in an off-site location outside the settlement, and iii) Disposal/reuse of the treated effluent, usually far from the point of origin.
Aside from its proven benefits, the centralised wastewater management system is nothing more than a transport system for human excreta and industrial waste to a central discharge point or a treatment system. By using valuable drinking water as transport medium, this system is wasteful of water and nutrients that could otherwise be easily treated and reused.

A centralised wastewater management system reduces wastewater reuse opportunities and increases the risk to humans and the environment in the event of system failure.

In the past, conventional thinking favoured centralised systems since they are easier to plan and manage than decentralised treatment units. This belief is partly true if municipal administration systems are centralised. However, experience reveals that centralised systems have been particularly poor at reaching peri-urban areas and informal settlements.

Centralised treatment systems are usually much more complex and require professional and skilled operators. Operation and maintenance of centralised systems must be financed by the local government often unable or unwilling to guarantee regular operation.
In a centralized approach, the ULB has to bear the capital and O&M cost of the infrastructure. However, taking into consideration the efficiency of collection of taxes in Indian cities, maintaining the infrastructure and providing services to the masses becomes more of a burden.

On the contrary, in a decentralized approach (depending on the selected sanitation system) the household (who is the consumer of the services) bears most of the cost. Since private service providers in terms of collection – transport and treatment are available, the costs get distributed among different stakeholders.

### 5.3 Decentralised Wastewater Management
In decentralised system, the solids are arrested in the on-site system. The greywater and effluent will be collected and transported to the decentralised wastewater treatment system using sewerage network. In decentralised treatment system, the dissolved and suspended solids in water will be treated and the treated water will be disposed/reused.

In centralised system the following requirements has to considered,

- The individual household toilets have to be with the containment system or on-site systems
- The sewerage network for collecting and conveying the greywater and effluent
- The decentralised wastewater treatment plant with mechanised or non mechanised treatment
Decentralised wastewater management decreases the risk associated with system failure. The probability of simultaneous failure of many small systems is significantly lower than failure of one system serving the entire community.
Decentralised treatment processes can be tailored to the quality of the wastewater stream generated by each separate subsystem and to the effluent quality required. The treatment requirements will vary considerably depending on the final destination of the treated wastewater (e.g., agricultural reuse, discharge into water bodies, infiltration).

Decentralised management increases wastewater reuse opportunities by keeping the wastewater as close as possible to the generating community. Demand for treated liquid waste in developing countries often comes from urban centres for use in public parks and urban agriculture. Where wastewater is used for irrigation, it is pointless to collect the waste flow in one location for treatment and subsequently distribute the treated effluent where it is needed.

Decentralised management may apply a combination of cost-effective solutions and technologies, which are tailored to the prevailing conditions in the various sections of the community. For example, a sewerage system and treatment works can be provided to highly developed and densely populated commercial and residential centres of a community. Sparsely populated housing neighbourhoods can be served by a settled sewerage system or dry sanitation systems where soil and groundwater conditions allow such options.

Decentralised management allows incremental development and investment in community wastewater systems. Settled sewers can be used to upgrade already existing decentralised systems such as septic tanks if necessary. New, independent and properly sized systems can be added to serve new and well-defined residential, industrial or commercial developments. In contrast, investments in centralised systems have to be made within a short time, thus burdening the local economy. Centralised systems are usually sized to handle wastewater flows planned to occur in 30-50 years. Centralised systems are initially often oversized but eventually become undersized.

### Constraints of decentralised systems

- Appropriate policy framework and enforcement.
- Capacity to plan, design, implement and operate.
- Coordination between government, private sector and civil society.
- Compatibility with knowledge, skills locally available.
- Number of small investments = BIG investment!
In a centralized approach, the ULB has to bear the capital and O&M cost of the infrastructure and they have to take into consideration the efficiency of collection of taxes in Indian cities, maintaining the infrastructure and providing services to the masses becomes more of burden.

On the contrary, in a decentralized approach (depending on the selected sanitation system) the household (who is the consumer of the services) bears most of the cost. Since private service providers in terms of collection – transport and treatment are available, the costs get distributed among different stakeholders.

5.4 Other Aspects of Liquid Waste Management
There are few aspects which has to be considered for the financial sustainability of the project:

i) The components of centralised sanitation systems are designed for 30 years of span except the pumping stations which are generally designed for 15 years of period

ii) The implementation of sewerage network is very slow and tedious process which effects in reach of utilities in peri urban and unorganised settlements

iii) Higher water supply to the limited people crossed the full capacity of the treatment systems even though sewerage network is not completed as per the planning

iv) To keep up the infrastructure, tax should be linked to metered water consumptions.

**Financial Sustainability**

- Components of Centralized Sanitation System are designed for 30 years. (exception pumping stations – designed for 15 years)
- Implementation of sewerage network is a slow and tedious process
- Peri urban areas and unorganized settlements are difficult to reach
- With increasing supply to limited number of people, the STP reaches to its full capacity even though the sewerage network is not completed as per the plan.
- To keep up the infrastructure, tax should be linked to metered water consumption.
Invariably, the sewers as a convention are designed for the ultimate projected population till next 30 years and the realization of the sewage volumes to use the designed sewer capacities results in idle volumes and idle expenditures. The underground sewers laid there merely become defunct with time and eventually go into repair. This is a non-productive expenditure, implying that the investment could have been utilized elsewhere like in decentralised treatment systems.

It’s a fact that while the investment on provision of sewerage is usually met out of capital grant funding, the cost of house service connections is to be met by the house owners when they occupy the property. Repeated road cuts become a perpetual affair over a long time which costs higher for single connection. As and when the houses are built, service connection requests arise. An approach that has been tried out is the provision of house service connection sewers even in the beginning itself and blank it at the property boundary and connect it only when the house gets built up and the applicant pays up the costs. An additional challenge is illegal connections by house owners and the impracticality of checking each and every such connection by the limited staff of the local body.
The capital costs are mostly carried out of grant funding whereas most of the time the O&M expenses are to be generated by the ULB. The meagre revenues generated by taxes and water and sewerage charges are too meagre to even break even in the local administration accounts, leave alone increasing the reserve funds. When an unwieldy coverage of a conventional sewerage is implemented, the problem gets compounded all the more because the house service connections do not keep pace and the revenues are meagre. Thus, even the cost spent on the house sewer connections becomes a virtual write-off over a period of time.

With enough political will and the creation of adequate incentives for businesses and policy makers alike, sustainable and productive sanitation can be a major contributing factor to the achievement of greener economies, fostering job creation and poverty reduction along the whole sanitation, wastewater treatment and re-use chain.
The multi barrier approach focuses more on integration of natural water treatment technologies in the urbanscape. These technologies treat perennial and intermittent water sources with special emphasis on resource recovery and reuse. The approach was successfully demonstrated through Indo-EU project called NaWaTech.

5.5 Planning of Sanitation Systems

Example of Kochi: In the case of Kochi, although centralized approach was logically the most favourable, the high ground table influenced the construction techniques and associated costs. Hence Kochi had to adopt decentralized approach in the form of septage management. Kochi has India’s first working Septage Management Plant.
The cities should integrate the new added areas to the municipal limits / urban agglomerations & newly developed areas (Eg. due to change in master plan) within the municipal limits, with the proposed system. Tools such as GIS helps to visualize the reach of the services and compare it with growth of the city. This helps to identify the section of the city which needs immediate attentions in terms of infrastructure. Such tools help to have planning and implementations in different phases.

**Key determinants for planning**

- Settlement: population size and density of a settlement.
- Physiographical parameters: soil type, topography, altitude, terrain and groundwater table.
- Land availability and social acceptance

Design of sewers, gradient of network, pumping requirements, technology options, construction techniques and associated costs
Use of GIS tools is also extended to real time data collection and monitoring the sewerage systems and sewage treatment plants (STPs).

A logical approach needs to be defined keeping in mind the local natural and built environment. Such logical framework is specific to area and needs to be altered or adopted from place to place. The logic diagram like these, helps to identify gaps in the sanitation chain and thereby zero down on the suitable options to complete the sanitation value chain.
Summary

- Liquid waste management is crucial for maintaining environmental health.

- Different levels of management fit appropriately in different urban and rural scenarios.

- Planning of sanitation systems needs to take into considerations affordability and long-term sustainability of infrastructure.

- Centralized and Decentralized management compliments and provides maximum sanitation coverage.

Session 07

Decentralised Wastewater Management

This is an exercise session – Kindly refer Part C: Workbook
Aspects of Decentralised Wastewater Management
8. Aspects of Decentralised Wastewater Management

Learning objective

- To understand various technical and non-technical aspects of decentralized wastewater management.
- To understand the importance of enabling environment to scale decentralized wastewater management.

Contents

Economic aspects
- Treatment quality
- Treatment cost
- Investment capital

Technical aspects
- Decentralization
- Construction
- Substrate

Legal aspects
- Sectors for application
- Political environment

Regulatory aspects
- Regulations and standards
- Bureaucracy

Social aspects
- Waste disposal in society
- Partners
Government Support: Political support at all levels is essential. Programme promoters should plan to invest considerable efforts to familiarise elected officials, senior sector staff and advisers with the concepts of the planned sanitation programme. The municipal authority is the focal point in both the creation of an enabling environment and implementation of the programme, as it is, along with senior staff, responsible for providing infrastructural services to all stakeholders within the municipality.

Legal Frameworks: Since many of the existing standards (national or municipal) are derived from those developed in industrialised countries under totally different conditions, they are often inappropriate. Unrealistic standards are sometimes applied to national and municipal aspects like health and building codes, but also to technical requirements in the field of water supply and wastewater management.

Institutional Arrangements: Institutional arrangements can, on the one hand, refer to the formation of special interest groups like CBOs; on the other hand, they can also refer to agreements and relationships between different groups, for example public, non-state, community-led and donor institutions. Local organization may provide support in the form of technical assistance. Examples: Public institutions, Non-state institutions, Community led institutions, Donor institutions.

Capacity Building: Many groups and organisations will need training and orientation if they are to be involved in a participatory planning process.

Financing: Financing is a key factor, which has to comply with administrative rules and provisions governing expenditure for local service improvements. National, regional and local level investment plans and budgetary allocations should prioritise the areas of greatest need. Rather than resorting to grants or subsidies, governments and their agencies should consider the establishment of a line of credit or the provision of equipment and materials against regular payments.
In this section, we will discuss on the economic aspects of the decentralisation approach. We have to understand the economic viability of decentralised wastewater management against the centralised wastewater management. The life-cycle cost analysis and cost benefit analysis are the tools for understanding the economic aspect.
In case of decentralised wastewater management, there is requirement of strict discharge standards for protecting the environment. These standards should be based on: i) The location of the discharge ii) Quantum of effluent and iii) Quality of influent.

In comparison with centralised treatment, the decentralised treatment and on-site treatment approaches can reduce around 30%-50% of the organic pollution load which are low cost options. If we will consider any further treatment then those are expensive and require aerobic treatment processes. For example, nitrogen, phosphorus or removal of specific contaminant is more expensive.
Generally, there are no financial returns and even less genuine interest with the administrations to invest in the wastewater treatment. As we know, there is polluters pay principle which demands the investment in the wastewater management when fines are imposed by the pollution control authorities. In India, there are many cities which are polluting rivers and the National Green Tribunal (NGT) has imposed fines on ULBs.

8.2 Technical Aspects
There are few technical aspects which we have to consider while planning for decentralised approach such as selection of simplified and appropriately designed technology. It’s a combination of non-technical staff with information pertaining to social matters and technical/engineering staff with the knowledge of implications on technical design which in matter results in appropriately designed technology for decentralised wastewater management.

In construction aspect, the information about the local availability of hardware required for deployment of technology helps to reduce the implementation cost of the project. The thorough technical knowledge of the design principals and structure details is very crucial for proper implementation of the treatment system.
In technical aspects, the study of wastewater characteristics i.e. quality, quantity and other parameters are important for technical staff while designing the system. The other parameters which can influence the design of the system like geography, structural and socio-economic conditions have to be studied. There is need of expertise to sample, analyse, design or select the appropriate treatment system.

8.3 Legal Aspects
There are different human settlements like low income areas, middle class housing colonies and high-income enclaves where DEWAM (Decentralized Wastewater Management) can be adopted suitably. Temporary bylaws should be made after taking into account the administration, financial and logistical capacities of the specific human settlements. One must focus on implementing DEWAM at different stages than only focusing the bylaws on discharge standards. A centralised maintenance service or control over a decentralised service is needed to guarantee sustainability of multiple DEWAM projects.

**Residential Application**

**SCENARIO 1: For High Income Enclaves**
- A residential unit to have its own complete DEWAM i.e. Anaerobic, Aerobic and Disinfection stage.
- Allows recycle and reuse of water at local level to maximize profits.

**SCENARIO 2: For Low and Middle Income Housing**
- Basic and robust anaerobic treatment should be provided at the house level.
- Solid free sewers to convey and collect water for further treatment at semi centralized level.
- Aerobic and disinfection to be done at semi centralized level.

There are different scenarios which we can focus considering the water sensitive designs. Scenario 1 covers the high-income enclaves where there should be separate DEWATS which allows recycle and reuse of water at local level to maximise the profits. Scenario 2 covers the low- and middle-
income housing where basic and robust anaerobic treatment should be provided at the house level and solid free sewers are laid to convey and collect water for further treatment at semi centralised level.

DEWAM can also be applied at commercial units as well as industrial estates considering the need of bylaws and awareness within the stakeholders.

Consideration of political environment is equally important as the administrative framework. The understanding of roles, responsibilities and recognizing the movers in the political perspective is important. Politicians need to realize that: i) Step by step approach that each stage of DEWAM remove certain pollutant to certain extent. ii) DEWAM promises permanency and guarantee of
treatment as it has simple and robust nature iii) Operation and maintenance of DEWAM should be kept absolute minimum to avoid future financial conflicts.

### Political Priorities

- Political and administrative preferences lean heavily towards large scale, centralized wastewater and sewerage systems.

**Industrial Economy v/s Environmental Health**

- Obstacle- unrealistic overly ambitious master plans
- Standards are borrowed from developed-industrialized countries having expertise through research and development in treatment technologies.
- In developing countries, these strict discharge standards are hardly followed because their application is too expensive- licensing/ import of technologies from developed countries.

### 8.4 Regulatory Aspects

**Regulatory Aspects**

Regulations and standards, Bureaucracy
There are many different systems for controlling the release of wastewater into the environment. One such system that is common in North America and Europe is a permit system: when used water or wastewater is discharged into the environment, a permit is issued which describes, quantitatively, the wastewater that can be discharged.

Parameters that may be described include the amount of water to be discharged (volume), the parameters to be monitored (e.g. BOD, total phosphate etc.) and their monitoring frequency (weekly, monthly etc.).

In many developing countries, such a permit system may not exist or if it does it may not be enforced. Household and community-based sanitation systems are generally beyond the scope of most regulations. However, their growing number will also increase the likelihood of regulations and standards being introduced.
In case of Malaysia, licenses are required for water supply or sewerage facilities or services. They have permit system which is required to discharge effluent from on-site sanitation systems or small decentralised STPs or centralised STPs.

In many developing countries, the responsibilities of different authorities are not clearly defined and reveal a lack of coordination/communication mechanisms between them. The responsibilities between central, regional and local authorities are also not well defined, thereby resulting in a slow and inefficient working manner. Sanitation programmes can be hindered by such bureaucratic procedures. Applications may be delayed because documents require the approval of various offices. Requests to different authorities can lead to contradictory answers.
8.5 Social Aspects

Everyone should understand that someone (i.e. decentralised level by specific stakeholders or city level by ULB administrations etc.) has to take initiative for managing the wastewater otherwise it will be difficult to manage in extreme stages. Appropriate waste disposal management and awareness in society or people is important to avoid the Illegal and Indiscriminate disposal of waste in surface water bodies.
This is an example, The Palace of Versailles, Paris which is one of the most iconic monuments among the architects but it's surprising that this monument doesn't have a single sanitation facility of toilet.

This is another example where Leonardo Da Vinci's Plague Inspired Model City of 1484 has the tier approach as the planned lower level canals are leading to the nearby water body to flush the waste away from the habitation.
If we can compare today’s waste management with historical approaches, it can be inferred that very little development has been made in the wastewater management approach.

In decentralised wastewater management, the collective participation of people is crucial. The collective participation leads to collection of capital investment for the project, land availability, easy permissions for trespassing of sewers over private land, collective finances for O&M.

Public willingness is low and is expected to increase only;

- in case of severe crisis or likelihood of substantial economic benefit
- as in case of reusing of wastewater
A project planning and execution always involves the participation of different stakeholders. In case of decentralised wastewater management projects, there are three major partners which are involved i.e. polluter as customer, government administration and private companies or project management firms.

<table>
<thead>
<tr>
<th>Partners</th>
<th>Polluter as customer</th>
<th>Government administration</th>
<th>Private companies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Under social agreement or threat of punishment would be obliged to contact the private engineering firms.</td>
<td>To form appropriate bye laws and oversee the implementation of the these bye laws.</td>
<td>Engineering &amp; design firms, EPC firms and Project Management firms.</td>
</tr>
<tr>
<td></td>
<td>Investment capital will come from individual, from bank loans or through subsidy from public funds.</td>
<td>Lack of enforcement and dissemination results into polluter being unaware of the bye laws.</td>
<td>Private firms are business oriented and wishes to have good profits for a product or service having low demand.</td>
</tr>
<tr>
<td></td>
<td>Neither bank want to give loans nor there are any subsidies from public funds in India.</td>
<td>Less demand for the product and service makes the product and service expensive.</td>
<td>Due to lack of knowledge, firms try to solve the problem with same approach.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Lack of incentives, due to which buying is less.</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

- Due to lack of enforcement of law, without financial returns, wastewater management will be always the last priority for the polluters.

- Black box approach can be followed in through understanding about the changing variable and reliable analysis monitoring is available.

- Political backing to the legal framework is needed.

- Regulatory framework to adopt to growing wastewater management assets in India.

- People’s participation is key for success of decentralized wastewater management.
Session 09

Understanding Faecal Sludge & Septage Management
9. Understanding Faecal Sludge & Septage Management

**Learning objectives**

- To realize the importance of FSSM as integral part of sanitation system in India
- To understand the basics of faecal sludge and septage quantification and type of desludging
- To understand the approaches for faecal sludge and septage management

**Contents**

Need and Challenges in FSSM

Planning of FSSM

- Quantification of Septage
- On demand vs Scheduled Desludging

Approaches of FSS Treatment

- Deep Row Entrenchment
- Co-treatment at STP or MSW Plant
- Faecal Sludge Treatment Plant (FSTP)
9.1 Needs & Challenges in FSSM

The percentage might be deceiving, but when we calculate the absolute numbers, the picture is horrifying:

- 37 million people practice open defecation in urban India
- 28 million people with individual toilets use insanitary methods of disposal of waste
- 43,117 MLD of untreated wastewater is discharged in water bodies or on land

Source: * Census of India 2011; † CPCG, Inverntorization of STPs (2015)
Insufficient infrastructure: The cities do not have adequate, properly designed infrastructure for managing the wastewater generated at city level. The coverage of the gravity sewer network and capacity to treat wastewater is limited. Hence, there is a need of acknowledging the need of FSSM. Through FSSM, the septage from the septic tank can also be well managed to reduce the pollution load on water resources.

Health and environmental implications: Water resources are usually shared by the cities. However, most of the cities having inadequate capacity to manage liquid waste, dispose it into the surface water bodies. The same surface water bodies are used as source of raw water by the cities in the downstream. Poorly designed gravity sewer system, also needs special attention. To clean the
deposits (silt, grit and solid waste) from the sewer network, sewage workers are employed. Most of the times, no suitable PPE is provided to these workers during the work.

Regulations: The regulations demand the ULBs to provide desludging services to the households having septic tanks. The faecal sludge and septage further needs to be treated before putting it for reuse/disposal.

Resource recovery: Faecal sludge and septage if treated appropriately can provide ample amount of nutrients. It can also be used as soil conditioner for improving the fertility and water retention properties of the soil. Some other treatment processes convert the bio char or fly ash. The bio char has decent calorific value and can be used in brick kilns small scale furnaces. It has good adsorption capacity and can be used to improve the soil conditions when mixed in appropriate quantities. Fly ash on the other hand is used for making bricks.

To manage the faecal sludge and septage, the sanitation system needs to be equipped for emptying and conveyance along with the treatment and reuse/disposal. Hence, there is a requirement of sanitation service chain. The service of emptying of septic tank to the households is given by the ULB or private operator. The mismanagement of service chain leads to greater negative impact on the environment and water resources.
In case of containment systems, space and affordability is the major challenge. Lot of houses did not have for standard twin pits or septic tanks. Since containment units were not focussed on during promotion under SBM, households looked at it as an extra expenditure. Hence most of the places, the containment systems were not build properly following the standard design as per IS Code 2470.

The challenges of containment systems in turn resulted in operational difficulties. The maintenance of such units became costly and insufficient. In most instances, the septic tank is located at the backside of the house, limiting access to it. In such cases emptying of the septic tank becomes a challenge as most of the vacuum trucks have the service limitation of 100 ft.
The main challenges faced by ULBs in the emptying and conveyance part is lack of equipment for providing desludging services, monitoring and irregular desludging frequencies. Due to insufficient equipment, in most cases there is a delay of one day to provide the desludging service. Apart from the ULB, in most cities there is a fleet of private operated vacuum trucks to also provide the desludging services. In absence of the proper regulations, the trucks are emptied in open drains or water bodies. Hence, a strict monitoring is required. Since there is no awareness regarding frequency of desludging of septic tanks and its importance, the demand for desludging is usually seen during emergencies such as back flow/ over flow from the septic tanks and strong stench from the toilets. Septic tank needs to be desludged at a certain frequency for maintaining its efficiency of sedimentation.

Most of the cities are not having FSTPs or STPs for treating the wastewater or septage. Hence, in absence of proper disposal point, the septage is indiscriminately disposed off in to the surface water bodies or on to the land. This leads to more pollution and health hazard when compared to open defecation.

There are no regulations at the ULB level for proper disposal of FSSM in absence of treatment facility. Since the solid content of faecal sludge and septage significantly high when compared to wastewater, indiscriminate disposal of it possesses a bigger health hazard. As a precautionary measure, the ULBs should at least practice scientific land disposal to reduce the spread of the pollution.
Current Challenges in FSSM

No priority to reuse of end products in the policies and regulations.
Low reuse even with high quality treated end product.

9.2 Planning of FSSM

Planning of FSSM
Quantification of FSS. On-demand vs Scheduled desludging
Quantification of the faecal sludge and septage and the data needed to arrive at the number largely depends on the type of desludging envisaged in the city. The quantification is real challenge in case of demand desludging where in depth understanding is required about the behaviour of the households towards emptying of their septic tanks. In case of schedule desludging, the data can be collected from the ULBs and couple it with sample surveys. However, to operationalize scheduled desludging appropriate regulations need to passed at the ULB level.

Quantification is necessary for gauging the scale of collection and transport network, identifying the number and types of discharge sites. It is also needed to arrive at required design capacity of FSTP and adopt a suitable financial model for sustaining FSSM services.
There are two methods of quantification—production method and collection method. The sludge production method is based on the standard septage generation rate. This method needs to be followed, in case where scheduled desludging needs to be practiced. The collection method is based on the quantity of the septage collected from the households by the existing vacuum trucks and its operators. This method needs to be followed in case demand desludging needs to be followed.

IS: 2470 Code for practice for Installation of Septic Tanks (Part 1: Design Criteria and construction)- 1985

Volume of digested sludge

0.00021 m³/cap/d = 76.65 L/cap/annum

US EPA: Technology Transfer Handbook on Septage Treatment and Disposal

Average per capita septage generation

230 L/cap/annum

The sludge production method, is based on the empirical number called volume of digested sludge in a septic tank. As per the IS 2470 which gives the practice of installation of septic tank the volume of digested sludge can be calculated as 0.00021 cum per person per day. In US, the septage generation rate varies from 190 L/cap/d to 265 L/cap/d; whereas the same in Germany is between 110 to 4380 L/cap/d. In the US EPA manual, the average per capita septage generation is recommended as 230 L per capita per day. However, this number needs to be used carefully as it differs depending criteria linked to dietary habit of the person and usage of the toilet.
The sludge production rate may vary depending on dietary habit. It’s not just the quantity but also the quality which may change due to this. The scarcity of the data pertaining to onsite sanitation systems (containment units) built is quite prevalent in the ULBs. Since the desludging frequency of not set, not all the faecal sludge which is generated every year is collected annually.

The sludge collection method relies on the inferences drawn from the structured interviews conducted with various stakeholders of FSSM. There are various factors affecting the collection and all are taken into considered during the data collection.

A structured interview consists of direct and indirect questions leading to data needed for assessing the quantity of faecal sludge and septage collected on a daily basis. Inferences need to be drawn from the responses received during the interviews.
Seasonal variation needs to be taken into consideration during the structured interviews. The graph on the slide shows that the average monthly collection differs for the same plant. In case of demand desludging, the demand for septic tank emptying might increase or decrease depending upon certain factors such as – high intensity rainfall leading to overflow of septic tank, decrease in ambient temperature leading to reduction in digestion rate. However, there are still some properties such as restaurants and commercial offices, public sanitation facilities which regularly desludge the septic tanks throughout the year.

Peaking factor needs to be understood while estimating the quantity of septage. The peaking factor caters to the variations in the monthly collection of septage. The peaking factor can range from 1.5 times to 4 times the monthly average. This needs to be fixed based on the inferences drawn from the structured interviews.
The quantity of the septage collected also depends on availability of discharge locations or demand of septage among farmers. If there are multiple discharge points available, then operators will not have to turn down the request of the septic tank desludging. The collection might also change depending upon the desludging fees. A large informal sector exists in emptying of septic tanks which goes unmonitored. Not all the collected septage reaches at the designated discharge point for treatment. In absence of proper monitoring, the FSTP might still receive less septage because of indiscriminate disposal.

**Demand desludging**

- Customers call the service provider directly to request for service
- Service may be performed by public or private operator

*Advantage*
- Provides the households more control over their facility as they determine when to request for service
- No requirement of database of septic tanks for MIS and collection of sanitation tax

*Disadvantages*
- Containment may be full before the request for service
- Lump sum payment at the time of service
- Expensive as the process is time consuming
- No opportunities for optimisation of the service
- No guarantee of income/month for the operators

**Challenges faced!**

- Number of discharge location or demand for the septage.
- In case of discharge at STP, affordability of discharge fee.
- A large informal sector is working in the business of "septic tank cleaning".
- Not all what is collected reaches the treatment plant.
- Identification of new legal discharge point might increase the frequency of the desludging.
Demand Desludging: Desludging of containment units such as septic tanks if a critical and should be practiced at a regular frequency. However, currently in India ULBs are practicing demand desludging. The provision of desludging services upon request by the household is called demand or “on demand” desludging. The household can opt for calling a private operator or the ULB for availing this service. Demand desludging has more disadvantages as compared to advantages.

<table>
<thead>
<tr>
<th>Scheduled desludging</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Regular and periodic emptying service provided to the household</td>
</tr>
<tr>
<td>• Zone by zone desludging</td>
</tr>
<tr>
<td>• Financial management with ULB</td>
</tr>
</tbody>
</table>

**Challenges**

• Requires a strong IEC and BCC.
• Difficult to be practiced in ULBs with low tax collection efficiency.
• Different sludge accumulation rates and FS storage capacities makes estimation of “optimal frequency” difficult.

**Advantages**

• Ensure the performance efficiency of septic tank
• Helps to preserve environmental health
• Avoids emergency situation- preventive measure
• Cost effective through program efficiency
• More affordable as the payments are spread out over time

Scheduled Desludging: It is a concept where the containment units are emptied at a fixed frequency decided by the ULB. The households need to be informed in advance regarding the service time. Financial management are to be done by ULB. The advantage of practicing scheduled desludging is that it helps the septic tank to perform consistently. Since the scum is still soft, the desludging process is quite easy and requires less time. The cost of desludging can be brought down by optimising the route. Since the cost of desludging reduces, it becomes more affordable to the households.

Although, there are advantages, scheduled desludging does face some challenges. Operationalising scheduled desludging requires a strong IEC campaign. If the desludging charges are to be recovered in the form of tax, then the ULB should focus of increasing and maintaining the tax collection efficiency. In this case, ICT can be used for improving the performance. Since the sizes of the tank and sludge accumulation rates can differ, the optimal frequency of the desludging cannot be gauged easily.
In this slide, we can understand the different treatment approaches in faecal sludge and septage management. The selection of treatment approach is dependent on the few specific factors like quantification and characteristics of the FSS, type of sludge, seasonal variations and local conditions. There are different treatment approaches as: i) Deep row entrenchment ii) Co-treatment at STP iii) Co-treatment in MSW iv) Faecal sludge treatment plant (FSTP).
Co treatment in STP

- Limiting factor:
  Organic & hydraulic loading on various treatment units of STP
- Application
  - At the Manhole Chamber before the inlet of STP
  - At the inlet of Screens of the STP
  - At the Sludge Management Process of the STP

Co-treatment of FSS in STP is one of the treatment approaches. It is mainly dependent on the effect of organic and hydraulic loading on various treatment units at STP. In this approach, FSS can be applied at different stages as: i) At the manhole chamber before the inlet of STP ii) At the inlet of screens of the STP iii) At the sludge management process of the STP.

Co treatment in MSW Plant

Co composting
- Dewatering of Sludge
- Dry solid content - in the range of 40 - 45%
- Provides nitrogen to the compost

Incineration
- Dewatering and Drying
- Dry solid content - at least 80% or higher
- Increases heat production

Dry Solid Content Requirements:
- Combustion- Dry solids content should be at least 80 per cent and preferably higher. The precise requirements will depend on the process used to burn the sludge.
- Composting- For optimum results, the dry solids content should be in the range 40–45 per cent. This corresponds to a water content which, in the case of compost, is normally referred to as its moisture content, of 55–60 per cent. It is possible to achieve solids contents in the
required range by increasing the retention time on sludge drying beds; however, the more usual approach is to co-compost dewatered sludge with materials that have both a higher carbon to nitrogen ratio and lower moisture content.

Deep Row Entrenchment

• Required appropriate plot of land with secured fencing.
• Deep trenches, filled with sludge and covered with soil.
• Advantages: Simple, low cost, limited O&M, low visible or odour nuisance.
• Limiting factor: Land and groundwater table, legislation.

**Deep row entrenchment (DRE):** It refers to the method where septage is fed to an excavated pit. Once the pit is fed with septage, the liquid seeps into the surrounding soil and the solids are arrested in the pit. Once the pit is full it is topped off with the excavated earth so that the solids can be stabilized. Once stabilized the content of the pit are converted into terra preta, which can be safely used in agriculture to improve the characteristic of the soil. DRE is very simple and low on operational expenditure. It does not create any visible olfactory nuisance. ULBs usually have heavy machinery for earth excavation readily available with them and hence, no specialised equipment is required to start practicing DRE. DRE cannot be practiced in low lying areas and region where ground water table is high.
Summary

• FSSM is required to preserve the environmental health as the dependency on onsite containment units is high in India.

• Current challenges involved in operationalizing FSSM.

• Methods and challenges of quantification of faecal sludge and septage.

• Pros and cons of demand and scheduled desludging.

• Primary approaches for faecal sludge and septage management.

Session 10

Faecal Sludge & Septage Management Planning

This is an exercise session – Kindly refer Part C: Workbook
Stakeholders Management
11. Stakeholders Management

**Learning objective**

- To understand the process of identifying and characterize stakeholders.
- To learn about stakeholders engagement and different tools involved in it.

**Contents**

- Stakeholder Analysis
  - Identification of Stakeholders
  - Characterisation of stakeholders

- Stakeholders engagement
  - Participation levels
  - Involvement tools
  - Milestones and cross cutting tasks
  - Distributing and formalising roles and responsibilities
Stakeholders is a group or organisation or individual that can influence or be influenced by the project. There are key stakeholders (e.g. ULBs or Households) and marginal stakeholders (e.g. sanitation sector experts or universities).
Why Stakeholder Analysis?

- Identify and characterize stakeholders
- Level of a project
  - Planning
  - Execution
  - Monitoring and evaluation
- Understand social and institutional context
- Planning of stakeholder’s participation
- Engage and build trust in stakeholders

- To identify who to involve and at which level of participation, at the different stages of the planning and implementation process
- To understand the social and institutional context
- To identify conflicts and interests in between the stakeholders.
- To clear the roles and responsibilities of each stakeholders in every stage of the projects.

Challenges faced with Stakeholders

Lack of participation: i) Lack of Influence and Recognition; ii) Lack of understanding the official language; iii) Lack of Money.

Constraints in the sludge emptying business: i) Costs of sludge transport; ii) Lack of available land for FSM activities.
Lack of resources and capacities: i) Lack of Management capacities; ii) Lack of human resources; iii) Laws are incomplete or not enforced; iv) Poor tax recovery.

Conflicts in-between stakeholders: i) Power games/competition; ii) Lack of communication and coordination within and between agencies; iii) Tensions in between formal and informal sectors.

Awareness and Behaviour: i) Lack of awareness

### Characterisation of stakeholders

<table>
<thead>
<tr>
<th>Stakeholder</th>
<th>Interest</th>
<th>Opportunities/Threats</th>
<th>Involvements Needs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Urban Local Bodies</td>
<td>Public Health Sanitation Work Sanitation fees</td>
<td>Power of Enforcement through regulatory framework Management of treatment units</td>
<td>Sensitization, need for capacity building, collaboration Institutional and regulatory framework, Enforcement Involvement of financing schemes</td>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Stakeholder C</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>…</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Main interest: Consultation with stakeholders should be carried out in order to determine how each interest can be taken into account in the future FS systems
- Strength: Establish what the process leader can count on
- Weakness: Establish where information, empowerment and capacity building is needed
- Opportunities/threats: Characterize the potential positive (negative) perspective of the project
- Relationship between stakeholders: Hierarchy, friendship, competition or professional link. Good, bad can decide which working groups can be built
- Impacts: Type of impact of the project on the stakeholder determines the measure needed to maximize positive impact and mitigate negative impact
- Involvement needs: The action required, results mainly from identified interest, weakness and potential.
Key stakeholders in a IWSM project are those whose interest and influence are most at stake. There are six criteria’s or attributes which are important for the selection of key stakeholders:

1. Activity linked with IWSM management
2. Political power
3. Potential support or threat
4. Ability to get funding
5. Ownership of a potential treatment site
6. Potential user of a treatment end product.

<table>

<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
It is important to differentiate between two different types of opportunities and threats; the influence over the project and the interest in the project. The tow concepts can be defined as,

**Influence:** Is the power that stakeholders have on the project i.e. to control which decisions are made, facilitate their implementation, or affect the project negatively.

**Interest:** Characterises stakeholders whose needs, constraints and problems are a priority in the strategy e.g. sludge service providers, end users, households and sanitation authorities.

---

**Exercise: Stakeholders Analysis**

**Groups:**
- Case A - FSTP Project at ULB
- Case B – Co-treatment of FS with STP at Town

**Steps has to followed by participants,**
1. Identify the stakeholders
2. Characterize the stakeholders
3. Select the key stakeholders
4. Influence and Interest Matrix

---

This is an activity session for face to face trainings – Kindly refer Part B: Learning Notes for activity instructions.
Stakeholder engagement or involvement is key for the successful implementation of integrated wastewater or septage management (IWSM) projects. It’s a step of planning process where stakeholders are included in order to take into account their needs, priorities and interests to achieve consensus and to remove opposition. It’s the key for sustainability of the project.
Choosing how to engage a stakeholder means choosing the appropriate participation level. The level of participation depends on what needs to be achieved with the targeted stakeholders.

**Information:** The objective is to enable the stakeholders to understand the situation, the different options and their implications. This is a one-way flow of communication. All the stakeholders concerned by IWSM need to be well informed in order to understand their role and the objectives of the project. It can be carried out through awareness raising campaigns or informative meetings or related field visits etc.

**Consultation:** The objective is to obtain the stakeholders feedback on the situation, options, scenarios, and/or decisions. This is a two-way communication. It allows interests, priorities, needs and concerns to be taken into account (e.g. through interviews carried out with different stakeholders at the beginning of the planning process). However, the stakeholders are not involved in decision making.
**Collaboration:** The objective is to work as a partner with the stakeholders on various aspects including the development of scenarios and the identification of the preferred solution. The power for taking decisions is shared between the stakeholders.

**Empowerment/Delegation:** The objective is to build the capacities of stakeholders so that they are able to make informed decisions, to take responsibilities for final decision making, and to assume their role and responsibilities once the IWSM system is implemented.
Once participation levels for each stakeholder have been defined, the involvement tools can be selected. For each participation level, there are number of possible involvement tools. Selection of involvement tool is depending on the goals, personalities and capacities of the stakeholders. It is also dependent on availability of resources required for conducting involvement programs. Stakeholder should have good knowledge of the local context. A minimal level of trust between stakeholders is also required. Few examples of involvement tools are individual meetings, informal or semi-structured interviews, focus group meetings, workshops, site visits, participatory mapping, surveys, media campaigns, mediation, logical frameworks, etc.
The selection of involvement tools should be done on a case-by-case basis as it depends on the different aspects of the local context like political framework, legal framework, institutional framework and social framework. Context specific involvement tools are used to make all the different stakeholder groups ready to make informed decisions and reach consensus where necessary.

### Milestones in IEC Campaign

**Milestones**

- Initial launching workshop.
- Validation workshop of selected options by all stakeholders.
- Validation workshop of the Action Plan.

**Cross cutting tasks**

- Raising awareness.
- Training and capacity building.

Usually, the level of participation of key stakeholders should increase as the process develops. From information at the very beginning stage, it should move towards collaboration, so that when it comes to implementation and operation, smooth collaboration between stakeholders is secured. The way in which participation levels evolve is context specific. However, the process is marked out by milestones corresponding to the end of phases, where participation levels are formally re-thought and where important changes can be decided for the next phase.

In participatory planning framework, there are different phases and milestone events. Three **main milestones** are identified for the involvement strategy of the project. i) initial launching workshop ii) validation workshop of selected options by all the stakeholders iii) validation workshop of the action plan.
In parallel, the planning process is usually marked by two participatory cross-cutting tasks: i) Awareness raising to a wide audience (i.e. not limited to key stakeholders and ii) Capacity building, which first aims to enable the key stakeholders to take informed decisions and then prepares the key stakeholders to endorse their role and responsibilities in the implementation and operation of the system.

### Exercise: Stakeholders Engagement

**Groups:**
- Case A - FSTP Project at ULB
- Case B – Co-treatment of FS with STP at Town

**Steps has to followed by participants,**
1. Participation levels as considering stakeholders in the project

This is an activity session for face to face trainings – Kindly refer Part B: Learning Notes for activity instructions.

### Summary

- Stakeholder analysis – a vital tool for understanding social and institutional context of a project.

- Identification and characterisation of stakeholders - provide early and essential information about who will be affected by and influence the project.

- Stakeholders engagement play vital role in sustainability of the project. It develops skills, trust, confidence required within the stakeholders to run the system.
Session 12

Faecal Sludge & Septage Treatment
12. Faecal Sludge & Septage Treatment

Learning objectives

- To understand the difference between faecal sludge and septage and its characteristics
- To learn the objectives and stages of treating faecal sludge and septage
- To understand non-mechanized and mechanized treatment units for faecal sludge and septage

Contents

- What is Faecal Sludge and Septage?
- Treatment objectives
- Treatment stages
- Treatment units
- FSTPs in India
12.1 What is Faecal Sludge & Septage?

What is Faecal Sludge?

- Contents of pits and vaults accumulating excreta and anal cleaning water.
- Very high solid content as compared to wastewater
- Characterised by-
  - fresh and yellowish
  - Low dewaterability
  - higher BOD
  - needs higher degree of treatment

Depending on the type of the containment system and its design and holding period, the content of the pits (human excreta) undergoes digestion. The containment unit such as pits or under designed septic tank results into faecal sludge, whereas the units such as septic tanks is the sludge holding capacity of 2-3 years or anaerobic treatment system such as digester produced septage. The content of septic tank has high TSS and TDS than wastewater.

Faecal Sludge is undigested fresh sludge which is yellowish in colour; has higher BOD and non-settleable solids. It needs higher degree of treatment.

What is Septage?

- Contents of septic tanks and vaults accumulating black water.
- Very high solid content as compared to wastewater
- Characterised by-
  - Well digested and black
  - High dewaterability
  - Lower BOD
  - Needs lower degree of treatment
Septage is well digested sludge which is black in colour; has higher content of settleable solids and requires lesser degree of treatment.

Source: Morup et al. 1998

This slide shows the characteristic of three different types of sludge depending upon its source—public toilet, septic tank (household) and STP. Thus, in case of Indian cities, it needs to be understood that different types of sludge might arrive at the treatment facility. In India, due to increasing number of decentralised wastewater treatment plants (aerobic as well as anaerobic) sewage sludge might also be received at the treatment facility. The degree of treatment required to treat these sludges is different.

**12.2 Treatment Objectives**

![Treatment Objectives](image)
One of the very important treatment objectives of the faecal sludge and septage is dewatering. Dewatering helps to reduce the volume of sludge to be handled and treated using other treatment mechanisms, hence it reduces the CapEx significantly. Separating the solids and liquid stream simplifies the treatment of the faecal sludge and septage and helps to optimise the process. Eg. In case of heat drying, dewatering will save significant amount of energy.

Dewatering can be achieved by gravity settling or filtration. However, it needs to be noticed that dewaterability of faecal sludge is less as compared to septage. Hence, in such cases, stabilisation is recommended before dewatering. Dewatering can also be achieved by increasing the solid content in the faecal sludge or septage. In case of pyrolysis or incineration, addition of dehydrating agent such as saw dust or wood chips is done to increase the solid content as well as the calorific value of the solids.

### Treatment objectives

**DEWATERING**

- Reduction of design capacities
- Simplifies treatment scheme
- Gravity settling or filter drying beds
- Dewaterability of faecal sludge and septage
  - Adding dry material to increase solid content
    - Wood chips, saw dust
    - Organic solid waste
  - Liquid fraction – high in ammonia, salts and pathogens

---

**PATHOGEN REMOVAL**

- FSS contains large amount of pathogenic micro organisms
- Significant health risk due to direct/in direct exposure
- Treatment up to adequate hygienic level

**Reduction/inactivation**

- Starvation
- Predation
- Exclusion
- Desiccation
- Temperature
The second most important objective is pathogen removal. Pathogen removal is important from the discharge and reuse point of view of the end products. Faecal sludge and septage is known to contain high amount of pathogens and hence indiscriminate disposal of it may result into cross contamination of the water resources. Reduction of pathogen is achieved by various ways as listed in the slide.

Starvation refers to starving the pathogen to death. Predation refers to introducing or allowing specific types of bacteria to eat (predate) the pathogens. Exclusion refers to physical exclusion of pathogens depending on their size using filters. Desiccation refers to reducing the moisture content to the level where the cell walls ruptures due to dryness. Pathogens are believed to reduced significantly at temperature above 60°C.

### Treatment objectives

**NUTRIENT RECOVERY**

- FSS contains significant concentrations of nutrients
- Can supplement synthetic fertiliser
  - Nitrogen based fertiliser is recovered from fossil fuel
  - Phosphorus is mined from finite resources such as ores
- If not managed properly can lead to;
  - Eutrophication and algal blooms
  - Contamination of drinking water

Nutrient recovery is a specific treatment objective which is very important when we are intending to use the end products as soil supplements for improving its characteristic. Faecal sludge and septage contain good amount of nutrients. If managed properly these nutrients can be used as supplement to synthetic fertilisers in agriculture. However, if not managed properly, it leads to eutrophication of water bodies and further it may lead to contamination of drinking water resources.
Stabilisation of faecal sludge is also one treatment objective. Faecal sludge contains more organic solids which needs stabilisation before it can be discharged into the environment. Stabilisation reduced the oxygen demand of the liquid fraction of the faecal sludge. The need of stabilisation can be assessed using parameters such as volatile solids, BOD and COD.

#### 12.4 Treatment Units - Non-Mechanised

- Treatment Units – Non Mechanised
- Settling Thickening Tank, Anaerobic digester, Planted/Unplanted drying beds, Co-composting
Settling thickening tanks are the simplest kind of treatment unit. It is the most commonly used treatment unit for solid liquid separation in case of faecal sludge and septage treatment. The separation takes place due to difference in the specific gravity of the solids and their masses. The fat – oil – grease which has lower specific gravity tends to float up on the surface of the water. Hence, in the settling thickening tank, the incoming sludge is given appropriate hydraulic retention time, where in the solids separate and the liquid effluent comes out from the outlet. The settled sludge then undergoes compaction due to hydraulic pressure from the top, resulting into thick dense layer suitable for pumping. Solids concentration is up to 12%.

Geotubes are long, relatively narrow, flexible bags fabricated from high-strength permeable textiles. The only opening in a bag is a connection to allow sludge to be discharged into it. Once
sludge has been pumped into a geotube, solids are retained in the bag while free water drains out through the permeable walls of the bag. Geotube are available in a variety of sizes. Geotube must be removed and replaced when they are full. This suggests that the permeable geotube option has an operational cost, which reduces its little viability as a dewatering option.

### Anaerobic digester

- **Organic matter** - Biogas (methane and CO₂) and digestate.
- **Advantages**: Production of biogas, reduction of sludge volume and odours.
- **Limiting factor**: High level of skilled operation and monitoring.

Anaerobic digester is used for stabilisation of solid in faecal sludge. Faecal sludge has higher content of slowly biodegradable COD. Hence to stabilise these solid and bring down the COD, anaerobic digester with retention time of 20-30 days is designed. The advantage of it is the production of methane gas which can be used for generating energy. Digestion also results in reduction in sludge volume and odour.

### Unplanted drying beds

- **Shallow filters with sand and gravels with under drain to collect filtrate.**
- **Application**: Climatic factor and types of sludge
- **Advantages**: Low cost and ease of operation.
- **Limitation**: Large footprint and odour potential

Unplanted drying beds are shallow filters with filter bed made out of combination of gravels and sand. The beds have under drain to collect the filtrate which is collected in filtrate sump by
gravity. The free water in the sludge drains out of the filter bed and the bound water is removed from the sludge by evaporation. The design of the sludge drying bed is based on the evaporation rate which is determined by the average temperature and humidity. The operational cycle of it ranges into weeks depending upon the local conditions.

**Planted drying beds**

- Unplanted drying bed with emergent macrophyte.
- **Application**: Climatic factor
- **Advantages**: Low cost and ease of operation.
- **Limitation**: Large footprint and odour potential

Planted drying beds are similar to the unplanted drying beds having macrophyte such as cattail, typha etc. In this case the bound water is removed by evapotranspiration. The difference between the planted drying bed and unplanted drying bed is the way they are operated and stabilization of sludge. Operational cycle is in months.

**Co composting**

- C:N Ratio = 20-30:1, Oxygen concentration: 40-60%, Particle diameter < 5 cm
- **Advantages**: Thermophilic condition, Pathogen inactivation
- **Limiting factors**: Technical and managerial skills

Co composting can be performed on the dewatered sludge. Sludge is rich in nitrogen and if mixed with organic solid waste to achieve C: N ratio of 30 then aerobic composting can be achieved.
Thermophilic condition is required for pathogen inactivation and hence care needs to be taken to achieve optimum temperature and maintain oxygen concentration between 40% - 60%. The advantage of the co composting is that it performs drying and pathogen reduction simultaneously and generates an end product with higher value in the market.

12.5 Treatment Units - Mechanised

Screw presses separate liquid from solids by forcing sludge through a screw or auger contained within a perforated screen basket. The screw diameter increases with distance along the shaft while the gap between its blades decreases so that the gap between basket, shaft, and flights continuously decreases and sludge is squeezed into a progressively smaller pace. The dewatered...
cake drops out of the end of the press for storage, disposal, or further drying on a drying bed or in a thermal dryer.

**Belt Press**

- Preconditioning
- Gravity drainage
- Low-pressure linear compression
- High-pressure roller compression and shear
- Work with inlet solids: < 0.5%
- Outlet solids: 15-25%

Belt filter presses separate liquid from solids, using gravity and applied pressure between fabric belts. The process typically involves four steps: preconditioning, gravity drainage, low-pressure linear compression, and high-pressure roller compression (and shear). After preconditioning, sludge passes through a gravity drainage zone where liquid drains by gravity from the sludge. It is then moved on to a low-pressure zone where two belts come together to squeeze out liquid from the solids, forcing liquid through the fabric belts. The dewatered sludge cake is then scraped off the belts for conveyance to the next stage of treatment or disposal. The belts are cleaned with high-pressure wash water after each pass.

**Paddle dryer**
Paddle dryer has paddle wings which are hollow from inside so that steam can be circulated from it. The paddle system is also encompassed into a jacket which is fed by steam. When raw material is introduced into the paddle dryer, the heat is transferred from the paddles to the sludge. The sludge moves in the forward direction and gets churned as it moves ahead. From the other end, the dried solids come out of the dryer. Dry air is introduced in the jacket to drive away the moisture laden air out of the dryer.

The simplest form of dryer is the direct rotary dryer. This consists of a cylindrical steel shell that rotates on bearings and which is mounted horizontally, with a slight slope down from the feed end to the discharge end. The feed sludge is mixed with hot gases produced in a furnace and is fed through the dryer. As it passes through the dryer, flights (fin-like attachments to the wall of the cylinder) pick up and drop the sludge, causing it to cascade through the gas stream. Moisture in the sludge evaporates, leaving a much dryer material at the discharge end of the dryer. The dried sludge is separated from the warm exhaust gas, part of which is recycled to the dryer while the remainder is treated to remove pollutants and is then vented to the atmosphere.
Belt dryers operate at lower temperatures than rotary drum dryers. The heat from the furnace is transferred to a thermal fluid, which heats the air in the dryer. The dewatered cake that is to be dried is distributed onto a slow-moving belt, which exposes a high surface area to the hot air.

Pyrolysis is the thermal decomposition of material at high temperatures in the absence of oxygen. It may be classified as fast, intermediate, or slow. Fast and intermediate pyrolysis require that the material undergoing decomposition remains in the reactor for seconds or minutes with temperature in between 700 – 900 °C. In slow pyrolysis, the main focus here, requires a retention time measured in hours and a temperature more, up to around 700°C. Pyrolysis differs from combustion in that little or no carbon dioxide is released during the process. Organic
material instead undergoes carbonization, or conversion into carbon in the form of hard porous charcoal. This material, which is called biochar, can be used as a soil amendment or as a fuel source.

### Selection of treatment mechanisms

<table>
<thead>
<tr>
<th>Treatment performance</th>
<th>Local context</th>
<th>O&amp;M requirements</th>
<th>Costs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Effluent and solids quality according to the discharge / reuse standards</td>
<td>• Characteristics of sludge (dewaterability, solids concentration, stabilisation, spreadability) • Quality of the frequency of the sludge to be received at treatment facility • Climate • Land availability and its cost • Interest in the enduse</td>
<td>• Availability of skilled persons for operation-maintenance and monitoring • Availability of spares locally in case of mechanical equipment.</td>
<td>• Investment costs covered (land acquisition, infrastructure, human resources, capacity building and training) • O&amp;M costs • Affordability for households and ULB</td>
</tr>
</tbody>
</table>

The selection of the treatment mechanisms depends on various factors which are listed in the slide i.e. treatment performance, local context, O&M requirements and costs.

### 12.6 FSTPs in India
Case Study - Videos

- Faecal Sludge Management – Jhansi
- Faecal Sludge Treatment Plant – Bhubaneshwar
- Faecal Sludge Management – Devanalli
- Faecal Sludge Management – Wai

Summary

- Characterization of faecal sludge and septage plays an important role in selection of treatment objective.

- FSS treatment facility consist of up to four stages, each having specific treatment objective.

- FSS treatment facility consists of multiple components to achieve the desired treatment objectives.

- Defining the right treatment objective is the key to selection of appropriate treatment components for FSS treatment facility.
Financial Aspects of Faecal Sludge & Septage Management
13. Financial Aspects of FSSM

Learning objective

- To look at different financial aspects regards to infrastructure project such as setting up a FSTP.
- To understand different financial models for operating FSSM citywide.

Contents

Financing FSSM
- Capital expenditure
- Operational expenditure
- Income and revenue
- Annualized cost

Financial flow models
- Discrete model
- Integrated model
- Sanitation tax model
- License model
- Incentivised model
Capital expenditure refers to all the one-time expenditure done to set up the treatment facility such as a FSTP. The percentage contribution of each component here changes depending upon the selection of treatment modules. For example: in case of treatment using settling thickening tank, sludge drying beds and DEWATS, the cost of civil cost will contribute largely to the total cost of the project. However, in case of mechanised dewatering and drying, the cost of electromechanical components will be on the higher side.
Operational expenditure is referred to the cost required to operate the treatment plant to treat and manage the sludge at the FSTP. This cost can be divided into two heads - direct and indirect cost. The direct cost refers to the cost which needs to be borne for actual operation and will vary depending upon the quantity of the sludge received at the FSTP. Indirect cost on the other hand refers to the cost to be borne irrespective of the quantity of the sludge received at the plant. Example is human resource cost and lease (in case the land is procured on lease for constructing FSTP).

**Operational expenditure**

- **Direct costs**
  - Expenditure to be borne in treating the faecal sludge and septage received at the treatment plant.
  - Cost of material for operation
  - Cost of power for operation
  - Cost of chemicals (if required any)

- **Indirect costs**
  - Expenditure to be borne even if faecal sludge and septage is not received at the treatment plant.
  - Human resource cost

**Income and revenue**

- **Discharge fee**
  - Fee collected from the collection and transport company to discharge faecal sludge and septage at the treatment plant.

- **Purchase price**
  - Revenue generated from the sell of end products such as soil conditioner, solid / liquid fuel, building material etc.

- **Budget support**
  - Financial support provided by the government authority (ULB) to the company operating and maintaining the treatment plant.
There are various streams of income and revenue for a FSTP. Standard streams are listed on the slide. Discharge fees refers to the tipping fee to be given by the desludging operator to the FSTP operator for taking the responsibility of the sludge for treatment and further disposal. Purchase price refers to the revenue generated by sale of the treated products. However, it needs to be understood that from these two streams, it is impossible to meet all the operational expenditure of the FSTP and hence budget support is needed. Budget support refers to the financial support provided by the government authority to the company which is operating and maintaining the plant.

### Annualized cost

\[
\text{Annual CapEx} = \text{CapEx} \times \frac{(1 + r)^N \times r}{(1 + r)^N - 1}
\]

\[
\text{Annualized Cost} = \text{Annual CapEx} + \text{OpEx} - R
\]

Where:
- CapEx: Capital expenditure
- \( r \): Rate of interest (bank rate – inflation rate)
- \( N \): Life span of the component
- OpEx: Operational expenditure
- R: Revenue

Annualised cost method is one method of life cycle analysis of infrastructure projects such as treatment plants. This method aggregates operation-maintenance cost, income and revenue and capital expenditure of the project into one single cost. It factors in the life of the civil, electromechanical and plumbing and electrical components based on their life spans. The O&M cost is factored in using rate of interest. Hence the method annualizes all the cost a given one cost which can be compared for all the technologies to choose suitable technology.
The slide gives cost analysis of the FSTPs in India. The plants marked in green are the plants which cater to both liquid and solid treatment completely. The blue bar shows the capital cost of the technology whereas the orange bar gives the O&M cost of the technology. Devanhalli and Phulera plant is based on DEWATS module, with feeding tank, stabilization unit, unplanted drying beds and co composting for solids treatment whereas for liquid treatment AS, ABR, AF and PGF have been installed. Bhubaneshwar is also based on DEWATS model, however, here settling thickening tank is used for separation of solids and liquid. At Warangal the treatment units are screw press followed by thermal drying and pyrolysis of the sludge. Liquid after dewatering is also treated separately.
The life cycle cost of these plants is shown in the slide above. It can be observed that cost of Bhubaneshwar plant is far less as compared to other three plants. Hence it can be seen that appropriate selection of the treatment units is necessary for optimising the cost of treatment. In LCA, the design capacity of the treatment plant can have an impact on the life cycle cost. It is also important to explore other options to manage septage for smaller capacities instead of having a full scale FSTP.

13.2 Finance & Contracting Models

Finance and contracting models
- Common Public FSSM Model
- Common Private Emplacing and Transportation Model
- Licensing Model
- Scheduled Deodging Sanitation Tax Model
- Incentivized Disposal Incorporating Licensing and Sanitation Tax Model
A commonly occurring scenario observed is the ownership and management of FSSM by the public sector for collection, transportation and treatment. Users of OSS approach local authorities, which are usually the municipality or the state-run water and sewerage companies, to provide emptying services. The service is provided for a prefixed price. The sludge collected is transported to a treatment plant or landfill site which is also owned and operated by a public utility or the local municipality.

In a commonly occurring scenario, when an emptying business is initiated by a private entity (mechanical or manual emptying), the households or businesses with on-site sanitation systems contact the private entity to provide emptying services on a fixed agreed tariff. Ideally, the private entity is required to transport and safely dispose the FS either to a treatment plant or to a designated disposal site, typically a landfill.
This business model is similar to the commonly occurring private emptying and transportation model. The key difference lies in the issuing of license/permits to the private truck operators by relevant public authorities to operate emptying businesses. Licensing helps in accounting for all emptying businesses in the city, and can potentially track these businesses to prevent illegal disposal of FS. The license/permit could be either a one-time fee or fees paid annually by the truck operators. The public authority issuing the license provides basic “dos and don’ts” to the truck operators, and they need to monitor for regulatory compliance by tracking the operations of private truck operators. The license is revoked, if the truck operator is found to be violating any regulations, especially engaging in the illegal disposal of FSS.

This business model has two key aspects: a) Sanitation tax collected from owners of OSS, and b) Mandatory scheduled desludging of tanks/pits. Sanitation tax is collected by the local authority either as a percentage of property tax or by the public utilities as a surcharge on water bills. Local authorities in discussion with the households using OSS set up a mandatory scheduled desludging plan. The user of the OSS does not pay for the desludging services unless they require an unscheduled service. The revenue generated from the sanitation tax is designed to cover the O&M cost of collection, transportation and treatment of FS. Local authorities can contract scheduled desludging to private truck operators to collect and transport sludge to designated disposal or treatment sites. The private entity receives payment based on the quantity of sludge delivered to the treatment plant (preventing illegal dumping) and the number of households that used the desludging service.
This model provides financial incentives to truck operators to encourage disposal of sludge at designated treatment sites. The objective of the model is to eliminate indiscriminate disposal of FS. The model does not charge disposal fees to truck operators to discharge FS at treatment sites, and instead the truck operators are paid a fixed price by the treatment plant for delivering FS.

**Summary**

- There are multiple types of cost which need to be considered by setting up a FSTP.

- Selection of the technologies should be done after looking at LCC of the project.

- There are multiple transfers which happen when FSSM is operationalized.

- Selecting appropriate contracting and financial transfer model is key to sustainability of the FSSM.

Session 16

Wastewater Treatment Principles
16. Wastewater Treatment Principles

Learning objectives

• To define and understand the objectives of wastewater treatment.
• To learn the underlying processes and their design parameters.
• To understand the different stages of treatment with focus on preliminary, primary and tertiary treatment.

Contents

• Objectives of wastewater treatment
• Treatment processes and stages
  • Primary treatment
  • Secondary treatment
  • Tertiary treatment
• Components of Sewage Treatment Plants
• Layout of STP
16.1 Objectives

Although the ultimate aim of wastewater treatment is to reduce the quantity of pollutants entering the natural environment, in some cases the specific goals can change from case to case. Specific goals of wastewater treatment can be as follows:

- To supply water to the industry such as cement, pipe manufacturing, stone cutting or thermal power plant as process water.
- To reduce the eutrophication of the surface water bodies such as lakes.
- To reduce the dependency on the rain and irrigation canal water by reuse in agriculture in drought prone areas.
- To improve the ground water table through indirect aquifer recharge techniques.
Wastewater treatment processes are of different types- Physical, Biological, Chemical and Photolytic. Physical processes are based on the physical characteristic of the wastewater constituents. Mainly it's the specific gravity of the constituent which assists the separation from the water. Biological processes rely on the microorganisms to carry out digestion of the organic matter in anaerobic or aerobic conditions. Biological processes are the main heart and soul of any wastewater treatment plant. Chemical processes rely on the use of chemicals either to treat the water (Eg. Ozonation to kill pathogens) or to assist the physical or biological processes (Eg. Alum or ferric chloride to coagulate the sludge). Photolytic processes rely on the photon in the light to treat the wastewater.
The slide shows different type of design parameters used to design wastewater treatment units. The importance of few design parameters may increase or decrease from case to case basis.

A waste treatment facility consists of different treatment stages combining different treatment processes. In case of wastewater treatment plant, after the preliminary treatment i.e. screening; the wastewater undergoes treatment in primary stage. In primary stage, the physical treatment processes are used to remove the easily settleable solids usually known as grit. The units which
provide primary treatment are listed in the slide above. In secondary stage, biological treatment processes remove the BOD and COD using the digestion process carried out by anaerobic and aerobic microorganisms. In the tertiary stage, chemical or photolytic treatment process is used to disinfect the wastewater.

16.3 Components of Headworks

Screens are used to remove the solid waste from the wastewater. Different sizes and configuration of the screens are available. Screens are either manually cleaned or mechanized to clean using a raking system as shown in the slide.
Screens are available in different types like coarse screen, fine screen or rotary drum screen. The specifications and design criteria's are given in the above slide.

In rotary drum screen, the screening or straining medium is mounted on a cylinder that rotates in a flow channel. The construction varies, principally with regard to the direction of flow though the screening medium. The wastewater flows either into one end of the drum and outward through the screen with the solids collection on the interior surface, or into the top of the unit and passing through to the interior with solids collection on the exterior. Drum screens are available in various sizes, from 0.9 – 2m in diameter and 1.2 – 4m in length.
Grit chambers are used to remove the inert easily settleable solids. Grit chambers are available in two types as shown in the figure: longitudinal flow and circular or vortex flow. In some cases, the grit chambers are also aerated to improve the separation of the solids from the wastewater. Grit chambers also remove the FOG – fat oil grease from the wastewater which is skimmed and stored separately from the grit. Grit Chambers are provided to:

- Protect moving mechanical equipment from abrasion.
- Reduce formation of heavy deposits in pipelines, channels and conduits.
- Reduce the frequency of digester cleaning caused by excessive accumulations of grit.

16.4 Components of Sewage Treatment Plant
Horizontal Flow – Circular Grit Chamber. In the horizontal flow circular type, the flow passes through the chamber in a horizontal direction and the straight-line velocity of flow is controlled by the dimensions of the unit, an influent distribution gate and a weir at the effluent end. The units are designed to maintain the horizontal velocity in between 0.25 – 0.4 m/s. These are normally designed to remove 95% of the 0.15mm diameter particle at peak flow.

Aerated Grit Chamber – In aerated grit chambers, air is introduced along one side of a rectangular tank to create a spiral flow pattern perpendicular to the flow through the tank. The heavier grit particles that have higher settling velocities settle to the bottom of the tank. Lighter, principally organic particles remain in suspension and pass through the tank. These chambers are normally designed to remove 0.21mm diameter or larger with 2 – 5min detention periods at peak hourly rate of flow.
In the vortex grit systems shown in the slide, the wastewater enters and exits tangentially. These are designed to capture/arrest grit or other similar matter; with a Specific Gravity $\geq 2.65$. The rotating turbine maintains constant flow velocity and its adjustable pitch blades promote separation of organics from the grit. The grit settles by gravity into the hopper in one revolution of the basin's contents. Solids are removed from the hopper by grit pump or an airlift pump. These types of chambers are designed to handle peak flowrates up to 0.3 m$^3$/s per unit.

**Application of Primary Clarifier:**
- Inorganic suspended solids or grit if it is not removed in grit chamber described earlier
- Organic and residual inorganic solids, free oil and grease and other floating material
- Chemical flocs produced during chemical coagulation and flocculation
- Mechanically cleaned tanks of standardized circular or rectangular design.
The key objective of secondary treatment of wastewater is oxidizes the dissolved and particulate biodegradable constitutes into acceptable end products. It also captures and incorporate the suspended and non-settleable colloidal solids into biological floc or biofilm form. In this treatment stage, we can transform or remove nutrients such as nitrogen & phosphorus and specific trace organic constitutes and compounds.
Benefits of Biological Treatment Processes:
- Most of the aerobic processes provide **carbonaceous BOD removal** and **nitrification**.
- All anoxic processes provide **denitrification**.
- Most of the anaerobic processes provide **carbonaceous BOD removal** and **stabilisation**.
- Combined processes provide carbonaceous BOD removal, nitrification, denitrification & **phosphorus removal**.

**Tertiary Treatment | Chlorination**

- Provides prolonged effect.
- Eliminates obnoxious odour.
- Residual chlorine is toxic to aquatic life.
- Highly corrosive, hence storage, shipping and handling pose a risk.

Chlorination is by far the most common method of wastewater disinfection and is used worldwide for the disinfection of pathogens before discharge into receiving streams, rivers or oceans. Chlorine is known to be effective in destroying a variety of bacteria, viruses and protozoa, including Salmonella, Shigella and Vibrio cholera. Chlorination plays a key role in the wastewater treatment process by removing pathogens and other physical and chemical impurities. Chlorine's important benefits to wastewater treatment are listed as follows: (a) Disinfection, (b) Controlling odour and preventing septicity, (c) Aiding scum and grease removal, (d) Controlling activated sludge bulking, (e) Controlling foaming and filter flies, (f) Stabilizing waste activated sludge prior to disposal, (g) Foul air scrubbing, (h) Ammonia removal.
Disinfection of water using ozone is advantageous compared to more traditional methods, such as chlorine or UV disinfection. Ozone effectively breaks down the lipid layers in the cell membrane. Firstly, ozone is more effective at deactivating viruses and bacteria than any other disinfection treatment, while at the same time requiring very little contact time.

An ultraviolet (UV) disinfection system transfers electromagnetic energy from a mercury arc lamp to pathogenic organism's genetic material (DNA and RNA). When UV radiation penetrates the cell wall of a pathogenic organism, it destroys the cell's ability to reproduce. The effectiveness of the UV disinfection is depending on the characteristics of wastewater, the intensity of UV radiation, the amount of time the microorganisms are exposed to the radiation and the reactor configurations.
The slide represents the flow diagram for activates sludge process-based sewage treatment plant. The upper part refers to the treatment of the wastewater however, the lower half shows the treatment of sludge.
The slide represents the flow diagram for trickling filter-based sewage treatment plant. The upper part refers to the treatment of the wastewater however, the lower half shows the treatment of sludge.

The slide here represents a decentralised wastewater treatment system (DEWATS). In this case there are three smaller sub systems. The system A caters to the black water. After anaerobic treatment consisting of anaerobic settler, anaerobic baffled reactor and anaerobic filter, the wastewater is disposed into the municipal sewers. The system B caters to grey water using a vertical flow constructed wetland. After treatment the wastewater is disinfected using dual media.
filter followed by UV. The system C caters to the sewage and is given anaerobic and aerobic treatment. Post disinfection the water from the system B and C is reused for toilet flushing and gardening.

The slide represents another decentralised wastewater treatment system of design capacity 100 KLD based on anaerobic up flow growth reactor and French reed bed system for treating the raw sewage directly. The treatment of the sludge produced in the anaerobic treatment was treated using planted drying beds. A decentralised wastewater treatment system hence can be mechanised with pumps, blowers, etc and does not essentially means DEWATS which is essentially completely natural without requiring electricity for treatment.

**Summary**

- The objectives of wastewater treatment should be clear before considering different options for treatment.

- Wastewater treatment technologies consist of different components.

- In case of FSTP, design of secondary treatment units needs to be individually tweaked for liquid effluent treatment.

- Nitrification, denitrification and aerobic treatment is needed order to achieve high standards of treatment.
Session 17

Wastewater Treatment Technologies
17. Wastewater Treatment Technologies

**Learning objectives**

- To understand in detail the Secondary Treatment Stage of the wastewater treatment and its types and working of each type.

- To understand the selection criteria for wastewater treatment technologies.

**Contents**

- Secondary Treatment
- Non-mechanised treatment systems
  - DEWATS
  - Waste Stabilisation Pond
  - Advanced Integrated Pond
  - Soil Bio Technology
- Selection criteria
- Mechanised treatment systems
  - Activated Sludge Process
  - UASB Reactor
  - Sequential Batch Reactor
  - Moving Bed Biofilm Reactor
  - Membrane Bio Reactor
The key objective of secondary treatment of wastewater is to oxidize the dissolved and particulate biodegradable constituents into acceptable end products. It also captures and incorporates the suspended and non-settleable colloidal solids into biological floc or biofilm form. In this treatment stage, we can transform or remove nutrients such as nitrogen and phosphorus and specific trace organic constituents and compounds.

### 17.1 Secondary Treatment
Benefits of Biological Treatment Processes:

- Most of the aerobic processes provide carbonaceous BOD removal and nitrification.
- All anoxic processes provide denitrification.
- Most of the anaerobic processes provide carbonaceous BOD removal and stabilisation.
- Combined processes provide carbonaceous BOD removal, nitrification, denitrification & phosphorus removal.

### Selection of appropriate processes

- Most of the aerobic processes provide carbonaceous BOD removal and nitrification.
- All anoxic processes provide denitrification.
- Most of the anaerobic processes provide carbonaceous BOD removal and stabilisation.
- Combined processes provide carbonaceous BOD removal, nitrification, denitrification & phosphorus removal.

### 17.2 Non-mechanised Treatment System

Non-mechanized treatment system

- Anaerobic Batch Reactor (ABR)
- Anaerobic Filter (AF)
- Constructed Wetlands (CW)
- Waste Stabilization Pond (WSP)
- Advanced Integrated Pond
**Anaerobic Baffle Reactor (ABR)**

- Contact between wastewater and resident sludge
- BOD: 70-95%
- TSS: 80% - 90%
- Low pathogen reduction
- HRT: 1 to 3 days

ABR is an improved version of the septic tank with multiple chambers having baffle pipes. Vertical baffles in the tank force the pre-settled wastewater to flow under and over the baffles guaranteeing contact between wastewater and resident sludge and allowing an enhanced anaerobic digestion of suspended and dissolved solids; at least 1 sedimentation chamber and 2–5 up-flow chambers.

**Anaerobic Filter (AF)**

- Reduces dissolved and non settleable solids
- BOD: 50 to 90%
- TSS: 50 to 80%
- Total Coliforms: 1 to 2 log units
- HRT: about 1 day

Anaerobic Filter (AF) is consists of multiple chambers where the baffle walls or pipes force the water to the bottom of the chamber and the water flows upwards while passing through the filter. AF is based on the attached growth micro-organisms. Dissolved and non-settleable solids are removed by anaerobic digestion through close contact with bacteria attached to the filter media.
Constructed Wetlands - Pre-treated grey or blackwater flows continuously and horizontally through a planted filter bed. Plants provide appropriate environments for microbiological attachment, growths and transfer of oxygen to the root zone. Organic matter and suspended solids are removed by filtration and microbiological degradation in aerobic, anoxic and anaerobic conditions. Constructed wetlands can be classified based on the flow of wastewater in the bed.

**DEWATS**

- An approach, rather than just a technical hardware package
- Treatment of wastewater flows 1 – 500 KLD
- Reliability, longevity and tolerance towards inflow fluctuation
- No sophisticated control and maintenance
- Works without energy- cannot be switched off!
- Guarantees permanent and continuous operation
- Is not a the best solution everywhere!
- Suitable where skilled and responsible operation and maintenance cannot be guaranteed
Waste stabilization ponds (WSPs) are large man-made basins in which greywater, blackwater or faecal sludge can be treated to an effluent of relatively high quality and apt for the reuse in agriculture or aquaculture. For the most effective treatment, WSPs should be linked in a series of three or more with effluent being transferred from the anaerobic pond to the facultative pond and, finally, to the aerobic pond.

The anaerobic pond is the primary treatment stage and reduces the organic load in the wastewater. The entire depth of this fairly deep man-made lake is anaerobic. Solids and BOD removal occurs by sedimentation and through subsequent anaerobic digestion inside the accumulated sludge. In a series of WSPs, the effluent from the anaerobic pond is transferred to the facultative pond, where further BOD is removed. The top layer of the pond receives oxygen from natural diffusion, wind mixing and algae-driven photosynthesis. The lower layer is deprived of oxygen and becomes anoxic or anaerobic. Settleable solids accumulate and are digested on the bottom of the pond. The aerobic and anaerobic organisms work together to achieve BOD reductions of up to 75%.
Advanced integrated wastewater pond systems (AIWPS), advanced integrated pond systems (AIPS) or advanced integrated ponds (AIPs) are an adaptation of waste stabilisation ponds (WSPs) systems based on a series of four advanced ponds: (1) An advanced facultative pond (AFP) containing a digester pit, which functions much like an anaerobic pond; (2) a high rate pond (HRP) covered with algae, similar to the facultative pond, which provide oxygen to aerobic bacteria for BOD oxidation and take up nutrients and further organics; (3) an algal settling pond (ASP); (4) and finally a maturation pond (MP) for solar disinfection and pathogen abatement. The effluent from the MP can be reused for agriculture or aquaculture and the nutrient rich algae can be applied as fertilizer or used as animal feed.

Soil Bio-technology is a terrestrial system for wastewater treatment which is based on the principle of trickling filter. In this system, combination of physical processes like sedimentation, infiltration
and biochemical processes are carried out to reduce the suspended solids, organic and inorganic contents of the wastewater. Suitable mineral constitution, culture containing native micro-flora and bio-indicator plants are the key components of the system. It is also known as Constructed Soil Filter (CSF). SBT systems are constructed from RCC, stone-masonry or soil bunds.

17.3 Mechanised Treatment System

An activated sludge process wastewater containing organic matter is aerated in an aeration basin in which micro-organisms metabolize the suspended and soluble organic matter. Part of organic matter is synthesized into new cells and part is oxidized to CO2 and water to derive energy. In
activated sludge systems the new cells formed in the reaction are removed from the liquid stream in the form of a floculent sludge in settling tanks. A part of this settled biomass, described as activated sludge is returned to the aeration tank and the remaining forms waste or excess sludge.

**UASB Reactor**

**ANAEROBIC SUSPENDED GROWTH BIOLOGICAL PROCESS**

- Recovery of biogas.
- Needs continuous and stable water flow and energy.
- BOD & COD: 60 to 90%
- TSS: 60 to 85%
- Low pathogen reduction and minimal removal of nutrient
- HRT: Min 2 hrs, 4 - 20 hrs

Industrial wastewater or blackwater flows into the bottom of an anaerobic upflow tank. Accumulated sludge forms granules. Micro-organisms living in the granules degrade organic pollutants by anaerobic digestion. The sludge blanket is kept in suspension by the flow regime and formed gas bubbles. A separator at the top of the reactor allows to recover biogas for energy production, nutrient effluent for agriculture and to retain the sludge in the reactor.

**Sequential Batch Reactor (SBR)**

**AEROBIC SUSPENDED GROWTH BIOLOGICAL PROCESS**

- Batch process consisting of 4 – 5 steps.
- Flexibility of treatment
- BOD, COD and TSS removal: up to 90%
- N removal if anoxic reaction is integrated.
- P removal is high
A sequencing batch reactor is a fill-and-draw activated sludge system for wastewater treatment. Oxygen is bubbled through the wastewater to reduce biochemical oxygen demand (BOD) and chemical oxygen demand (COD), producing a high-quality effluent with a low turbidity and nitrogen levels. The SBR accomplishes equalization, aeration, and clarification in a timed sequence in a single reactor basin. By varying the operating strategy; aerobic, anaerobic, or anoxic conditions can be achieved to encourage the growth of desirable micro-organisms.

MBBR is a highly effective biological treatment process based on a combination of conventional activated sludge process and biofilm media. The MBBR process utilizes floating media within the aeration and anoxic tanks. The microorganisms consume organic material. The media provides increased surface area for the biological microorganisms to attach and grow. The increased surface area reduces the footprint of the tanks required to treat the wastewater. The treatment process can be aerobic and/or anaerobic and operates at high volume loads.
The Membrane Bioreactor or MBR is based on the conventional wastewater process, but the separation of micro-organisms is performed by filtration with membranes. The MBR has some distinctive advantages compared with the conventional treatment systems: (1) Very compact design, (2) High quality effluent, (3) Low sludge production.

17.4 Selection Criteria

Selection Criteria
In this slide, the parameters or factors are listed which has to be considered while the selection of appropriate wastewater treatment technology.

### Check list for Selection

- Influent characteristics
- Climatic constraints
- Finance
- Performance
- Reliability
- Complexity
- Compatibility
- Environmental constraints
- Chemical requirements
- Energy requirements
- Resource requirements
- Land availability
- Treatment residual and its disposal
- Inhibiting and unaffected constituents

### Technology Comparison

This slide includes the comparison of wastewater treatment technologies considering the land area required, energy requirement, capital investment required and operational cost. It can be observed that the natural treatment systems have require least energy and operational cost than other mechanised treatment technologies.
Other parameters

Focus on life cycle cost of the project derived in terms of cost of treated water over the period of its designed life.

Sewage Treatment Plants – 15 Years

- When you pay too much- you may lose a little money
- If you pay too little- you may lose everything

Spend a bit more money up front to reduce the operating and maintenance costs

This slide includes the other parameters which need to be considered while selection of the technologies like capital expenditure, operational expenditure and life cycle cost of the project.

Summary

- Secondary treatment stage is the most important stage in wastewater treatment in STP.

- Various combination of treatment processes take place in the secondary stage for achieving the reuse or discharge standards.

- Non mechanized and mechanized options are possible for wastewater treatment.

- Capital Cost of the project should not be the driving principle for selection of wastewater treatment technology.
Case Studies of Sewage Treatment Plants & Faecal Sludge Treatment Plants in India
18. Case Studies of STPs & FSTPs in India

Learning objectives

• In this session participants will be introduced with different case studies of STPs and FSTPs of India
• Detail components and treatment units of STPs and FSTPs of India

Contents

Case Studies of India
• Sewage Treatment Plant (STP)
• Faecal Sludge Treatment Plant (FSTP)
18.1 STP in India

STP in India

- COEP Hostel Campus, Pune (Decentralised)
- Ordinance Factory, Nagpur (Decentralised)
- Sewage Treatment Plant, Erandwane, Pune (Centralised)

COEP Hostel Campus, Pune

Type of project
Greywater segregation, wastewater treatment and reuse for toilet flushing and gardening

Beneficiaries served
Approx. 2000 students + personnel

Plant capacity
140 KLD wastewater & 35 KLD greywater

Executing institution
ESF, Pune

Type of project:
Greywater segregation, wastewater treatment and reuse in an urban area (College of Engineering, Pune Hostel Campus) with anaerobic treatments and constructed wetlands, full-scale demonstration project.

Project period:
- Start of construction: May 2014
• End of construction: June 2015
• Start of operation: June 2015
• Ongoing monitoring period planned for: 6 months
• Project end: December 2015

**Project scale:**
- Number of people covered: max. 1500 students + personnel
- Size of treatment plant: 175 m³
- Plant capacity: 140 m³ of wastewater, 35 m³ of greywater
- Total investment (in EUR): 160,000.00

**Address of project location:** COEP Hostel Campus, Shivajinagar, Pune – 411005, Maharashtra (India)

**Planning institution:** NAWATECH consortium (www.nawatech.net)

**Executing institution:** College of Engineering Pune (COEP)

The slide here represents a decentralised wastewater treatment system (DEWATS). In this case there are three smaller sub systems. The system A caters to the black water. After anaerobic treatment consisting of anaerobic settler, anaerobic baffled reactor and anaerobic filter, the wastewater is disposed into the municipal sewers. The system B caters to grey water using a vertical flow constructed wetland. After treatment the wastewater is disinfected using dual media filter followed by UV. The system C caters to the sewage and is given anaerobic and aerobic treatment. Post disinfection the water from the system B and C is reused for toilet flushing and gardening.
This slide includes the photos of the natural wastewater treatment system at COEP hostel campus, Pune.

**Type of project:**
The NaWaTech project aims to optimize the use of different urban water flows by treating each of these flows via modular natural systems appropriated to urban and peri-urban areas of India. The system considered in this case study is located in the Ordnance Factory Ambajhari (OFAJ), Gov. of India, Nagpur, and Maharashtra, India. It provides sewage management for at least 1,000 populations equivalent (PE). It consists of a main treatment line (anaerobic pre-treatment and horizontal flow constructed wetland (HF-CW) as well as a sludge drying reed bed for sludge mineralization generated from the primary clarifier) and a pilot line with a French type constructed wetland system and a short rotation plantation (SRP). It provides water for a multipurpose lawn to prevent the use of fresh water in gardening.
**Project period:**
- Start of construction: September 2014
- End of construction: November 2015 (estimated)
- Start of operation: December 2015 (estimated)
- Ongoing monitoring period planned for: Seven months
- Project end: June 2016

**Project scale:**
- Number of people covered: 1,000 PE
- Water flow: 100 m³/d
- Total investment (in EUR): 94,900 € for capital and O&M for one year

**Address of project location:** Ordnance Factory Ambajhari (OFAJ), Gov. of India, Ministry of Defence, Nagpur, Maharashtra 440014, India

**Planning institution:** NaWaTech consortium (www.nawatech.net)

**Executing institution:** National Environmental Engineering Research Institute (NEERI, Nagpur)

**Supporting agencies:** Department of Science and Technology (DST), Government of India; Ordnance Factory Ambajhari (OFAJ), Nagpur Govt. of India; European Commission (7th Framework Programme).

---

The slide represents another decentralised wastewater treatment of design capacity 100 KLD based on anaerobic up flow growth reactor and French reed bed system for treating the raw sewage directly. The treatment of the sludge produced in the anaerobic treatment was treated using planted drying beds. A decentralised wastewater treatment system hence can be mechanised with pumps, blowers etc and does not essentially mean DEWATS which is essentially completely natural without requiring electricity for treatment.

**STP – Decentralised Amanora Township, Pune**

- **Type of project**
  Wastewater treatment and reuse for toilet flushing and gardening with MBR and SBR technologies

- **Beneficiaries served**
  Approx. 300 P.E.

- **Plant capacity**
  SBR - 10 KLD and MBR - 30 KLD

- **Executing institution**
  ESF, Pune
- Number of people covered: 200-300 population equivalent (PE)
- Size of treatment plant: 52 m² of land footprint (including housing for the equipment)
- Wastewater is treated in an SBR (10 m³/day) and in an MBR (30 m³/day)
- Type of reuse: gardening and flushing
- Energy supply: 380 V/3 Phases/50 Hz

**Erandwane STP, Pune**

**Type of project**
Centralised Wastewater treatment system with Activated Sludge Process (ASP) Technology

**Beneficiaries served**
Approx. 5 Lakh P.E. (Erandwane, Kothrud Area)

**Plant capacity**
ASP - 50 MLD

**Executing institution**
Pune Municipal Corporation, Pune

**Erandwane STP, Pune**

- Wastewater Inlet → Screening and Grit Removal Chamber → Primary Clarifier → Aeration Tank (Extended Aeration) → Chlorine Disinfection System → Secondary Clarifier → Treated Water → Centrifuge De-watering Unit → Sludge for Disposal or Reuse → Aerobic and Anaerobic Sludge Digester
The city of Bhubaneshwar is planning for sewered sanitation system, however, until the sewerage network and STP is developed, Odisha Water Supply and Sewerage board installed a SeTP with design capacity of 75 KLD. The treatment chain is elaborated in the slide above. The plant treats the solids and liquid completely and has been designed as a zero liquid discharge plant. The bio solids are reused for plantation around the plant and the liquid is also completely utilised in and around the plant to maintain the green spaces.
After the receiving ramp, the septage is emptied into the screen chamber, which segregates the solid waste from the septage. The septage then flows into the STT where the solid liquid separation happens and the sludge undergoes thickening process. The thickened sludge is then pumped to the sludge drying beds for further dewatering and drying. The dried solids are then co composted with the organic waste (dry waste from the lawn and plants in the SeTP premise). The liquid from the STT flows under gravity to the anaerobic treatment (anaerobic settler, anaerobic baffled reactor and anaerobic up flow filter) followed by aerobic treatment in constructed wetlands. Finally, the clarified water comes to polishing pond where is disinfected and kept aerated using cascade aeration.

**FSTP, Wai**

- **Capacity** - 70 KLD
- **Area of installation (Sq.ft.)** - 19,602
- **Inlet** - Faecal Sludge and Septage (FSS)
• **Outlet**- Treated water and Biochar
• **Year of Installation**- 2018
• **Capital investment (INR)**- 1.8 Crores
• **Scale of service**- City-wide coverage of 8500 HH approx. within municipal boundary
• **Treatment time**- 12 hrs
• **C.O.D. (outlet)**- 34-80 ppm
• **B.O.D. (Outlet)**- 18-24 ppm

**System description**
In Wai, septic tanks of household toilets are emptied by a private contractor (Sumeet Facilities Pvt. Ltd.), and septic tanks of community and public toilets are emptied by WMC's vacuum tankers. The collected faecal sludge and septage is taken to the 70 KLD treatment facility consisting of the following components:

- Septage receiving station
- Holding tank
- Dewatering unit
- Pasteurization unit
- Dryer and Pyrolysis unit
- Wastewater treatment unit

Pyrolyzation of septage with a limited oxygen supply destroys all pathogens present in excreta, and provides fast volume and mass reduction, a net energy output (heat and electricity) and a usable end product in the form of biochar is produced. Biochar provides excellent soil enrichment when used with compost. The treated liquid from the treatment plant is used for landscaping within the premise and for washing vacuum tankers and solid waste collection vehicles.
The Faecal Sludge Management Plant in Narsapur is being developed as a sanitation resource park on 1 acre of land which was gifted to the municipality by one of its residents. The plant on its own stands on 0.4 acres of land.

**Key Features of the treatment plant:**
- 15 KLD Capacity
- Remote monitoring capability
- Bio-safe process in a modular/ scalable configuration
- Quick setup
- All weather systems
- Process Output: Treated Water for – agriculture, urban greening and industry. Biochar can be used as a soil – amendment and in filtration process.
FSTP at Warangal was commissioned in the year 2017 having the capacity of 15 KLD, different subsystems are integrated together to treat the faecal sludge which includes both civil and electromechanical components. The system comprises of components such as septage receiving station with screenings and grit chambers, pasteurization unit, solid-liquid separation, dryer, pyrolizer, heat exchanger and dewatered effluent treatment system. These different subsystems integrated together form a complete plant that can process faecal sludge to biochar.

About NIUA
NIUA is a premier national institute for research, capacity building and dissemination of knowledge in the urban sector, including sanitation. Established in 1976, it is the apex research body for the Ministry of Housing and Urban Affairs (MoHUA), Government of India. NIUA is also the strategic partner of the MoHUA in capacity building for providing single window services to the MoHUA/states/ULBs.

About SCBP
The Sanitation Capacity Building Platform (SCBP) is an initiative of the National Institute of Urban Affairs (NIUA) to address urban sanitation challenges in India. SCBP, supported by Bill & Melinda Gates Foundation (BMGF) is an organic and growing collaboration of credible national and international organisations, universities, training centres, resource centres, non-governmental organisations, academia, consultants and experts. SCBP supports national urban sanitation missions, states and ULBs, by developing and sourcing the best capacity building, policy guidance, technological, institutional, financial and behaviour change advice for FSSM. SCBP provides a unique opportunity for:

• Sharing and cross learning among the partner organisations, to pool in their knowledge resources on all aspects of urban sanitation capacity building;

• Developing training modules, learning and advocacy material including key messages and content, assessment reports and collating knowledge products on FSSM. Through its website (scbp.niua.org), SCBP is striving to create a resource centre on learning and advocacy materials, relevant government reports, policy documents and case studies;

• Dissemination of FSSM research, advocacy and outreach to State governments and ULBs.

Its strength is its ability to bring together partners to contribute towards developing state sanitation policy, training of trainers and training content development, technical and social assessments, training programme delivery, research and documentation.
Integrated Wastewater and Septage Management—A Planning Approach
